About This Guide

This Guide explains how to use VNC remote access and control software from RealVNC to connect two computers over a network, and control one from the other.

Applicable software

All the information in this Guide applies to connections established between a client computer running the latest version of *VNC Viewer* and a host computer licensed to use *VNC Server (Enterprise)*. Unless otherwise stated, this combination is assumed. To see how to set these applications up, read *Getting the computers ready to use on page 11*.

Note that general principles of remote control, and information relating to particular supported features, also apply to connections established between any combination of the products and license types listed below.

VNC Server (with different licenses applied)

- *VNC Server (Personal)*
Contains most RealVNC remote control features. A thirty day trial is available.
- *VNC Server (Free)*
Contains basic remote control features.

For more information on licensing *VNC Server*, start with *Licensing VNC Server on page 72*.

VNC Viewer

- *VNC Viewer for Java*
This application is freely available to download on demand from *VNC Server (Enterprise)* or *VNC Server (Personal)*.
- *VNC Viewer Plus*
This application is available to purchase from www.realvnc.com/products/viewerplus/.
- *VNC Viewer for iOS*
This application is available to purchase from the Apple App Store. Visit www.realvnc.com/products/ios/ for more information.
- *VNC Viewer for Android*
This application is available to purchase from Google Play. Visit www.realvnc.com/products/android/ for more information.

To understand restrictions for connections established between particular combinations of products and license types, see *Connectivity and feature matrix on page 13*.

Intended audience

There is no such thing as a typical RealVNC user or remote control session. This Guide therefore has more than one audience in mind:

- Chapter 1 is a general introduction to remote control, intended for everybody.
- Chapters 2 through 5 are intended for users who want to connect to and control a remote computer.
- Chapters 6 and 7 are intended for users who want to set up the remote computer to be controlled.

This Guide is intended to be operating system-agnostic, as far as possible. Information related to specific operating systems is clearly marked.

Conventions

Screen captures are of Windows 7 unless otherwise stated. Dialogs and other artifacts may appear different under UNIX/Linux and Mac OS X, or versions of Windows with different themes, but the principle is the same.

Technical Support

You can contact Technical Support if you have a valid support and upgrades contract to use *VNC Server (Enterprise)* or *VNC Server (Personal)*. To see whether this is the case, examine the **Details** section of the **VNC Server** dialog, or run the command `vnclicense -list`.

For more information, visit www.realvnc.com/support/.

Related information

Visit www.realvnc.com for:

- Supported platforms, operating systems, and system requirements.
- Instructions on how to install and uninstall *VNC*.
- Release notes, Knowledge Base articles, forums, and FAQs.
- Information relating to earlier incarnations of *VNC*.
- Information relating to other RealVNC products and solutions.

Introduction

This Guide summarizes how to use *VNC* remote access and control software from RealVNC to connect two computers over a network and take control of one (the *host computer*) from the other (a *client computer*), irrespective of where the two are in the world, or incompatibilities they may have in platform, architecture, or operating system.

VNC consists of two components: *VNC Server* and *VNC Viewer*. All the information in this Guide applies to connections established between a client computer running the latest version of *VNC Viewer* and a host computer licensed to use *VNC Server (Enterprise)*. For a list of other products and license types to which some information may also apply, see *Applicable software on page 7*.

Getting the computers ready to use	11
Connectivity and feature matrix	13
What to read next	17

Principles of VNC remote control

To connect to and control one computer from another:

- An application called *VNC Server* must be running on the host computer; that is, on the computer you want to control. To obtain the latest version of *VNC Server*, download *VNC* from www.realvnc.com/download/vnc/. Follow the instructions to license it, or consult *Licensing VNC Server* on page 72.

Note: You may be able to control computers running alternatives to *VNC Server*. For more information, see *Connecting to VNC-compatible Server applications* on page 15.

- An application called *VNC Viewer* must be running on the client computer; that is, on the computer you are sitting in front of, and want to exercise control from. The latest version of *VNC Viewer* is available to download from www.realvnc.com/download/viewer/.

Note: You may be able to control computers using alternatives to *VNC Viewer*. For more information, see *Connecting from alternatives to VNC Viewer* on page 15.

- Host and client computers must be connected to the same TCP/IP network. This can be a private network such as a LAN or VPN, or a public network such as the Internet. Note that firewalls and routers must typically be configured before an Internet connection can be established. See *Connecting over the Internet* on page 28 for more information.

For information on how to set these applications up, see *Getting the computers ready to use* on page 11.

Consider the following example environment:

A. Client computer (typically a laptop or desktop) running VNC Viewer. **B.** Client device (handset or tablet) running VNC Viewer for iOS or Android. **C.** Host computer (typically a workstation or server) running VNC Server. **D.** Router exposing a public network address for Internet connections to the host computer.

To start a remote control session, run *VNC Viewer* and identify *VNC Server* on the host computer you want to control. Once authenticated, *VNC Viewer* displays the host computer's desktop in a new window, and you can take control using the client computer's keyboard and mouse. You can run applications, change settings, and access data on the host computer exactly as you would be permitted to do were you sitting in front of it. See *a picture*.

Note: By default, *VNC Server* permits other users to connect to the host computer at the same time as you. You may be sharing control.

VNC remote access and control software solves different problems for users with different requirements, from the family member troubleshooting computer problems over the Internet to the system administrator configuring devices remotely in an enterprise environment. To find out how to get the information you need from this Guide, see *What to read next* on page 17.

Getting the computers ready to use

Before you can establish a connection, certain operations must be performed on both host and client computer.

This section addresses the client computer user and assumes the same person is able (that is, is physically present and has sufficient privileges) to configure the host computer as well. If not, contact a system administrator or a host computer user.

Note: Some operations need only be performed once. Others must be performed before each connection.

Setting up the host computer

1. Ensure the host computer is turned on, has a functioning operating system, and is connected to a network to which the client computer can also connect. This can be:
 - A private network such as a LAN or VPN, if both computers are co-located at home or in a typical small office environment.
 - A public network such as the Internet for most other kinds of connection, and especially those made from an Internet café, a public Wi-Fi hotspot, or over a mobile (cellular) data network (3G/GPRS/EDGE).
2. Download and install *VNC* from www.realvnc.com/download/vnc/, and license the *VNC Server* component. The credentials of a user with administrative privileges on the host computer are required. For more information on licensing, start with *Licensing VNC Server* on page 72.
3. If you are connecting over a public network such as the Internet, it is very likely the host computer will be protected by at least one firewall. If so, each must be configured to allow network communications through to the port on which *VNC Server* is listening, which is 5900 by default. See *Allowing network communications through a firewall* on page 31 for more information.
4. If you are connecting over a public network such as the Internet, it is very likely the host computer will be protected by at least one router. If so, each must be configured to forward network communications through to the port on which *VNC Server* is listening, which is 5900 by default. See *Configuring a router to forward network communications* on page 29.

5. Make sure *VNC Server* is running on the host computer and that it can accept incoming connections. See *Step 1: Ensure VNC Server is running on the host computer* on page 20 for more information.
6. Find out the network address of *VNC Server*. If you are connecting:
 - Over a LAN or VPN, this must be a private address, which is that of the host computer itself. See *Connecting within a private network* on page 27 for more information.
 - Over the Internet, this must be a public address, which is that of a router or similar device. See *Connecting over the Internet* on page 28 for more information.
7. Find out the credentials required to authenticate to *VNC Server*. By default, if you are connecting to:
 - *VNC Server (Enterprise)* or *VNC Server (Personal)*, you require the user name and password of a user account with administrative privileges on the host computer. Note at least one account on the host computer must have a password set; see *Authenticating using host computer user credentials* on page 98 for more information.
 - *VNC Server (Free)*, you require a password specific to VNC. For more information, see *Authenticating using a VNC password* on page 103.

Note: If you cannot perform these operations and a host computer user is present, you may be able to jointly perform a *reverse connection*. See *Establishing a reverse connection* on page 107 for more information.

Setting up the client computer

1. Ensure your client computer is turned on, has a functioning operating system, and is connected to the same network as the host computer.
2. Download *VNC Viewer* from www.realvnc.com/download/viewer/, and save the file to an appropriate location (depending on the download package chosen, you may need to extract it first). Under UNIX and Linux, you must also make the file executable, for example by running the command:

```
chmod +x <VNC Viewer>
```

Note: Alternatively, you can download and install *VNC* on the client computer, and just run the *VNC Viewer* component, since it does not require a license key. If you do this, *VNC Viewer* can be started from the menu system of most operating systems, which may be more convenient, and in addition you can save connections to *VNC Address Book*.

3. If your client computer is protected by a proxy server, specify the details of that proxy server. For more information, see *Connecting via a proxy server* on page 36.

Connectivity and feature matrix

You can use *VNC Viewer* to connect to:

- The latest version of *VNC Server* incorporated in *VNC*.
- Previous versions of *VNC Server* incorporated in *VNC Enterprise Edition* or *VNC Personal Edition*.
- VNC-compatible Server applications from third parties.

Note that the latter two may require configuration before a connection can be established, and that not all RealVNC remote control features are available once connected.

Note: This section assumes you are connecting from the latest version of *VNC Viewer*. For alternatives, see *Connecting from alternatives to VNC Viewer* on page 15.

Connecting to VNC

You can establish a connection from *VNC Viewer* to the latest version of *VNC Server* incorporated in *VNC* providing the following conditions are met.

	VNC Server		
	Enterprise	Personal	Free
VNC Viewer	No configuration required.	On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum.	On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum or Always on.

Note: For information on configuring *VNC Viewer* encryption, see *Step 4: Request an encrypted connection* on page 22.

Restrictions

- Connections to *VNC Server (Personal)* cannot be encrypted using ultra-secure 256-bit AES.
- Connections to *VNC Server (Free)* cannot be encrypted at all.
- The credentials you enter to log on to your *client* computer cannot be used to authenticate automatically to *VNC Server (Personal)*.
- The credentials you enter to log on to the *host* computer cannot be used to authenticate to *VNC Server (Free)*.
- Connections to *VNC Server (Free)* are not optimized for performance.
- *VNC Viewer for Java* cannot be downloaded from *VNC Server (Free)*.

Once a connection is established, you cannot:

- Exchange files with *VNC Server (Free)*.
- Print *VNC Server (Free)* files.
- Chat with other *VNC Server (Free)* users.

Connecting to VNC Enterprise Edition or VNC Personal Edition 4.6

You can establish a connection from *VNC Viewer* to *VNC Server* incorporated in *VNC Enterprise Edition* or *VNC Personal Edition* 4.6 without configuration.

Restrictions

The credentials you enter to log on to the host computer cannot be used to authenticate to *VNC Personal Edition*.

Connecting to VNC Enterprise Edition or VNC Personal Edition 4.5 or earlier

You can establish a connection from *VNC Viewer* to *VNC Server* incorporated in *VNC Enterprise Edition* or *VNC Personal Edition* 4.5 or earlier providing the following conditions are met.

	VNC Server	
	VNC Enterprise Edition 4.5-	VNC Personal Edition 4.5-
VNC Viewer	On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum.	On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum.

Restrictions

- Connections to *VNC Enterprise Edition* and *VNC Personal Edition* cannot be encrypted using ultra-secure 256-bit AES.
- The credentials you enter to log on to the host computer cannot be used to authenticate to *VNC Personal Edition*.

Once a connection is established, you cannot:

- Exchange files with *VNC Enterprise Edition* or *VNC Personal Edition* 4.3 or earlier. Note under Windows, there are also certain restrictions when connected to version 4.5 and 4.4 as well.
- Print *VNC Enterprise Edition* or *VNC Personal Edition* 4.4 or earlier files.
- Chat with *VNC Enterprise Edition* or *VNC Personal Edition* 4.4 or earlier users.

Connecting to VNC-compatible Server applications

You can establish a connection from *VNC Viewer* to the following (selected) third party VNC-compatible Server providing certain conditions are met.

	VNC-Compatible Server		
	Apple Remote Desktop or Screen Sharing built-in to Mac OS X	Remote Desktop or Desktop Sharing built-in to Ubuntu	Community projects such as TightVNC or UltraVNC
VNC Viewer	<p>On the host computer, VNC viewers may control screen with password must be turned on, and a password set.</p> <p>On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum or Always on.</p>	<p>On the host computer, Allow other users to view your desktop and Allow other users to control your desktop must be turned on.</p> <p>On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum or Always on.</p>	<p>On the client computer, <i>VNC Viewer</i> encryption must not be set to Always Maximum or Always on.</p>

Restrictions

Note that *no* RealVNC remote control features are available for connections to host computers running VNC-compatible Server applications. In particular, connections cannot be encrypted.

Connecting from alternatives to VNC Viewer

You can connect to the latest version of *VNC Server* from the following alternatives to *VNC Viewer*:

- *VNC Viewer for Java*. See *Connecting from VNC Viewer for Java* on page 15.
- *VNC Viewer Plus*. See *Connecting from VNC Viewer Plus* on page 16.
- *VNC Viewer for iOS*. See *Connecting from mobile devices* on page 16.
- *VNC Viewer for Android*. See *Connecting from mobile devices* on page 16.
- VNC-compatible Viewer applications from third parties. See *Connecting from VNC-compatible Viewer software* on page 16.

Connecting from VNC Viewer for Java

You can use any modern web browser to download *VNC Viewer for Java* from *VNC Server (Enterprise)* or *VNC Server (Personal)* on demand, and then immediately connect.

Note: You cannot download *VNC Viewer for Java* from *VNC Server (Free)*.

You do not require the credentials of a user with administrative privileges on the host computer in order to use *VNC Viewer for Java*. For more information, see *Chapter 4, Connecting From A Web Browser* on page 49.

Restrictions

Once a connection is established, you cannot:

- Exchange files with the host computer.
- Print host computer files.
- Chat with other connected users, or with a host computer user.
- Save connections.
- Scale the host computer's desktop.

Connecting from VNC Viewer Plus

You can purchase and install *VNC Viewer Plus* from www.realvnc.com/products/viewerplus/.

In order to make a standard VNC connection, select **VNC** from the **Connection Mode** dropdown on the **VNC Viewer Plus** dialog.

Restrictions

Once a connection is established, you cannot save connections to *VNC Address Book*.

Connecting from mobile devices

You can purchase and install:

- *VNC Viewer for iOS* from the Apple App Store. Visit www.realvnc.com/products/ios/ for more information.
- *VNC Viewer for Android* from Google Play. Visit www.realvnc.com/products/android/ for more information.

Restrictions

Once a connection is established, you cannot:

- Exchange files with the host computer.
- Print host computer files.
- Make the connection view only.
- Chat with other connected users, or with a host computer user.

Connecting from VNC-compatible Viewer software

Other organizations offer VNC-compatible Viewer applications, for example Remote Desktop Viewer built-in to Ubuntu.

In order to allow connections to *VNC Server (Enterprise)* or *VNC Server (Personal)*, make sure:

- Encryption is turned off. See *Changing the encryption rules* on page 109.
- System authentication is turned off. See *Relaxing the authentication rules* on page 104.

Restrictions

Note that *no* RealVNC remote control features are available for connections from client computers running VNC-compatible Viewer applications. In particular, connections cannot be encrypted.

What to read next

RealVNC remote control software can be used in many different ways to solve many different kinds of problem. There is no such thing as a typical RealVNC user or remote control session.

For example, you may be sitting in front of the client computer and want to know how to use *VNC Viewer* to control a remote host. There may or may not be a host computer user for you to communicate with, and you may be sharing the host computer's desktop—and therefore control—with other users. Or you may be sitting in front of the host computer and need to know how to set up *VNC Server* for multiple incoming connections. You may be connecting within a corporate network, in which case a system administrator might be available to help with connection issues. Or you may be helping friends or family over the Internet, and have to negotiate firewalls and routers on your own.

RealVNC remote control software is designed to be as useful out-of-the-box to as many people as possible. However, there is virtually no limit to the ways in which it can be configured to suit your requirements and environment. Some chapters in this User Guide are targeted at more experienced users, likely to require the power of changing options – system administrators setting up *VNC Server* for virtualization or remote configuration, for example. Other chapters, especially the first two, should be useful for all users.

- To walk through establishing your first connection from a client computer running *VNC Viewer* to a host computer running *VNC Server*, see *Chapter 2, Getting Connected* on page 19.
- To learn how to use features of *VNC Viewer* to enhance your experience of controlling a host computer, read *Chapter 3, Using VNC Viewer* on page 33.
- If you want to control a host computer from a web browser instead of *VNC Viewer*, read *Chapter 4, Connecting From A Web Browser* on page 49.
- To see how to exchange information between client and host computers, read *Chapter 5, Exchanging Information* on page 59.
- To learn how to configure *VNC Server* on the host computer, and for advanced topics such as running multiple instances of *VNC Server*, see *Chapter 6, Setting Up VNC Server* on page 71.
- By default, *VNC Server* establishes authenticated and, depending upon your license, encrypted connections. To learn more about security, and how to relax the rules if you consider it safe to do so, read *Chapter 7, Making Connections Secure* on page 97.

Getting Connected

This chapter aims to help the majority of users get started establishing their first connection from a client computer running the latest version of *VNC Viewer* to a host computer licensed to use *VNC Server (Enterprise)*. For a list of other products and license types to which some information may also apply, see *Applicable software on page 7*.

Note: This chapter assumes both host and client computers are set up correctly. For more information, see *Getting the computers ready to use on page 11*.

Connecting is usually a straightforward process but because computer networks must be secure, problems can occasionally occur. This chapter offers help for the most common connection issues but it may also be necessary to consult the RealVNC web site, or contact Technical Support. Alternatively, if you are connecting within a private network such as a corporate Local Area Network (LAN), consult your system administrator.

Contents

Step 1: Ensure VNC Server is running on the host computer	20
Step 2: Start VNC Viewer on the client computer	21
Step 3: Identify VNC Server running on the host computer	21
Step 4: Request an encrypted connection	22
Step 5: Connect to VNC Server	23
Troubleshooting connection	26

Step 1: Ensure VNC Server is running on the host computer

VNC Server may already be running on the host computer, but to make sure, and if you have access, follow the appropriate instructions for the host computer's platform below. If you do not have access, contact your system administrator or a host computer user.

- Under Windows, select **RealVNC > VNC Server** from the **Start** menu, or double-click the *VNC Server* desktop icon, if available. Note administrative privileges are required to perform this operation.
- Under UNIX/Linux, select **Applications > Internet > VNC Server (User Mode)** from the menu system, or search for this application using the standard facility.

Note: If no menu system or search facility is available, open a Terminal window, run the command `vncserver-x11`, and press the ENTER key. Note you should *not* do this as a user with administrative privileges.

- Under Mac OS X, navigate to the **Applications > RealVNC** folder, and double-click the **VNC Server** program. Note administrative privileges are required to perform this operation.

The **VNC Server** dialog opens:

If the status bar is green, *VNC Server* should be licensed and configured correctly for connections.

If *VNC Server* is not licensed, or is not configured correctly, the status bar turns red. Click the **Show** button that appears, and follow the instructions. For more information, consult *Troubleshooting connection* on page 26.

Step 2: Start VNC Viewer on the client computer

This section assumes *VNC Viewer* is available on the client computer. For more information, see *Setting up the client computer* on page 12.

To start *VNC Viewer*, double-click an appropriate icon, or open a Command or Terminal window and:

- Under Windows, run the command `<VNC Viewer>.exe`
- Under UNIX/Linux, run the command `./<VNC Viewer>`
- Under Mac OS X, run the command `<VNC Viewer>.app/Contents/MacOS/vncviewer`.

The **VNC Viewer** dialog opens:

Step 3: Identify VNC Server running on the host computer

You must uniquely identify *VNC Server* running on the host computer you want to control.

If you are connecting within a private network such as a LAN, enter the network address of the host computer itself in the **VNC Server** dropdown. This address can take the following forms:

- A host name for the host computer, for example `john.doe`. (Note the computer may not have a host name.)
- An IP address for the host computer in IPv4 format, for example `192.168.0.133`.
- An IP address for the host computer in IPv6 format within square brackets, for example `[2001:db8::1]`. (Note IPv6 may not be enabled.)

If you do not know the network address of the host computer, start with *Connecting within a private network* on page 27.

If you are connecting over the Internet, and the host computer is protected by a router, then enter the network address of the *router* in the **VNC Server** dropdown instead. If you do not know the network address of the router, see *Connecting over the Internet* on page 28.

In the following example, the host computer is identified by an IPv4 network address:

Typically, a host computer needs no further identification. This is because, by default, *VNC Server* listens for network communications on a registered port, 5900. Carry on from *Step 4: Request an encrypted connection* on page 22.

There may be circumstances, however, when *VNC Server* is listening on a different port. This can occur if the host computer is running UNIX/Linux, or if more than one instance of *VNC Server* is running on the host computer. If, when you try to connect, you see an error message similar to the following:

```
Connection refused (10061)
```

then you probably need to qualify the network address with a port number. For more information, see *Qualifying a network address with a port number* on page 30.

Step 4: Request an encrypted connection

You can request that the connection be encrypted.

Encryption ensures that data exchanged between the two computers while the connection is in progress cannot be intercepted by third parties. Note that *VNC Server* determines whether or not connections are *actually* encrypted (requesting encryption is not a guarantee).

Note: For more information on encryption, and security in general, see *Chapter 7, Making Connections Secure* on page 97.

By default, connections to:

- *VNC Server (Enterprise)* are encrypted using industry-standard 128-bit AES. You can request that this be enhanced to ultra-secure 256-bit AES.
- *VNC Server (Personal)* are encrypted using industry-standard 128-bit AES.
- *VNC Server (Free)* cannot be encrypted. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if security is important to you.

By default, in the **VNC Viewer** dialog, the **Encryption** dropdown is set to `Let VNC Server choose`:

If you are connecting to:

- *VNC Server (Enterprise)* or *VNC Server (Personal)*, it is recommended you retain this option unless you have a good reason to either request that encryption be:
 - Enhanced to 256-bit AES for connections to *VNC Server (Enterprise)* only.
 - Turned off.

For more information on these operations, see *Changing the encryption rules* on page 109.

- *VNC Server (Free)*, do not change this option. Doing so may prevent you connecting. For more information, see *Connectivity and feature matrix* on page 13.

Step 5: Connect to VNC Server

To connect to *VNC Server*, click the **Connect** button at the bottom of the **VNC Viewer** dialog:

You are guided through steps to ensure that the connection is legitimate and secure.

Checking the signature

If you are connecting to *VNC Server (Enterprise)* or *VNC Server (Personal)*, you may see a message similar to the following:

No signature has been stored for this VNC Server, so its identity cannot be identified.

The VNC Server signature is 2d-99-e9-11-aa-73-e6-f9.

Do you wish to accept the signature and continue connecting?

If you have access to the host computer, or can communicate with a host computer user, you can check that *VNC Viewer* is connecting to the correct destination (and not, for example, to a malicious third party) by comparing this signature with that displayed in the **Get Started** section of the **VNC Server** dialog:

If you see any other message referring to the *VNC Server* signature, it is recommended you do *not* connect. For more information on this security feature, see *Uniquely identifying VNC Server* on page 118.

Click the **Yes** button to continue connecting to *VNC Server*.

Acknowledging the encryption status

If the connection is unencrypted, you are prompted to acknowledge that sensitive information may not necessarily be secure:

If this is unacceptable and you are connecting to *VNC Server (Enterprise)* or *VNC Server (Personal)*, you may be able to turn encryption on. Click the **Cancel** button and see *Changing the encryption rules* on page 109 for more information. Otherwise, click **Continue**.

Entering authentication credentials

You may be required to enter a user name and/or a password:

By default, if you are connecting to:

- *VNC Server (Enterprise)* or *VNC Server (Personal)*, enter the credentials of a user with administrative privileges on the host computer. If you:
 - Do not know such credentials but have access to the host computer, you may be able to find them out, or alternatively register your own credentials. If you do not have access, contact a system administrator or a host computer user.
 - Know that the primary user account does not have a password set (likely for friends and family only), then you must change the default authentication mechanism, or disable authentication altogether.

For more information, start with *Authenticating using host computer user credentials* on page 98.

- *VNC Server (Free)*, enter the VNC password, leaving the **Username** field blank. If you do not know this password but have access to the host computer, you may be able to reset it; see *Authenticating using a VNC password* on page 103 for more information. If you do not have access, contact a system administrator or a host computer user.

Click the **OK** button. If the connection succeeds, *VNC Viewer* displays the host computer's desktop in a new window on the client computer. Carry on from *The VNC Viewer user experience* on page 38.

If the connection fails for any reason, start with *Troubleshooting connection* on page 26.

Note: Once connected, you can save the connection details so you can quickly reconnect without having to remember the network address and authentication credentials. For more information, see *Appendix A, Saving Connections* on page 121.

Troubleshooting connection

This section provides additional information to help you connect.

If, after reading this, you still cannot connect:

1. Consult www.realvnc.com.
2. If you have a valid support and upgrades contract to use *VNC Server (Enterprise)* or *VNC Server (Personal)*, contact Technical Support. Start with *Technical Support* on page 8 for more information.
3. If all else fails, and providing you are in a secure environment and a host computer user is present, you can ask that person to connect to you. For more information, see *Establishing a reverse connection* on page 107.

Licensing VNC Server

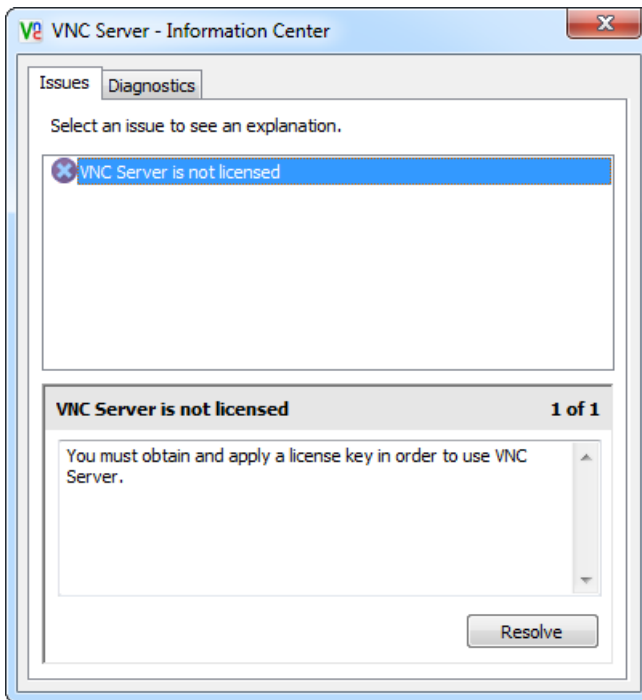

VNC Server must be licensed. If it is not, users cannot connect.

Note: VNC Viewer does not need to be licensed.

If VNC Server is not licensed, the status bar on the **VNC Server** dialog turns red:

Click the **Show** button to see more information:

Click the **Resolve** button to start the process of licensing VNC Server, and follow the instructions. See *Licensing VNC Server on page 72* for more information.

Connecting within a private network

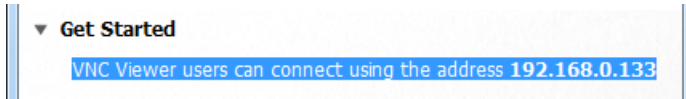

If both client and host computers are managed within a closed network environment such as a LAN or VPN, you are connecting within a *private network*. This is common in corporate and other enterprise environments, and may also be the case if you are connecting two computers at home.

To connect within a private network, enter the network address of the host computer itself in the **VNC Viewer** dialog, for example:

If you do not know the network address of the host computer:

- And you do not have access to it, you will need to consult your system administrator or a host computer user.
- And you *do* have access to the host computer:
 - a. Open the **VNC Server** dialog. *More on this dialog.*
 - b. Examine the appropriate section of the **Get Started** section:

Connecting over the Internet

If you are connecting over the Internet (for example, to friends and family, over a cellular network, or in to the office on the move), it is very likely that the host computer will be protected by a router or similar device acting as a communication gateway and public interface.

Note: The host computer is also very likely to be protected by a firewall. For more information, see *Allowing network communications through a firewall* on page 31.

To connect over the Internet, enter the network address of the *router* in the **VNC Viewer** dialog, for example:

If you do not know the network address of a host computer's router:

- And you do not have access to the host computer, you will need to ask a host computer user either to follow the instructions below, or to visit www.whatismyip.com.
- And you *do* have access to the host computer:
 - a. Open the **VNC Server** shortcut menu. *More on this menu.*
 - b. Choose **Information Center** and, on the **Diagnostics** tab, click the **Test Internet Connection** button.

- c. Click the **Start** button. RealVNC attempts to contact the host computer over the Internet. Providing the host computer is connected to the Internet, the network address of an intermediary device is revealed:

VNC Server appears to be behind a NAT router with IP address 212.44.6.81. You will need to configure that router to forward port 5900 to this computer before you can connect to VNC Server over the Internet.

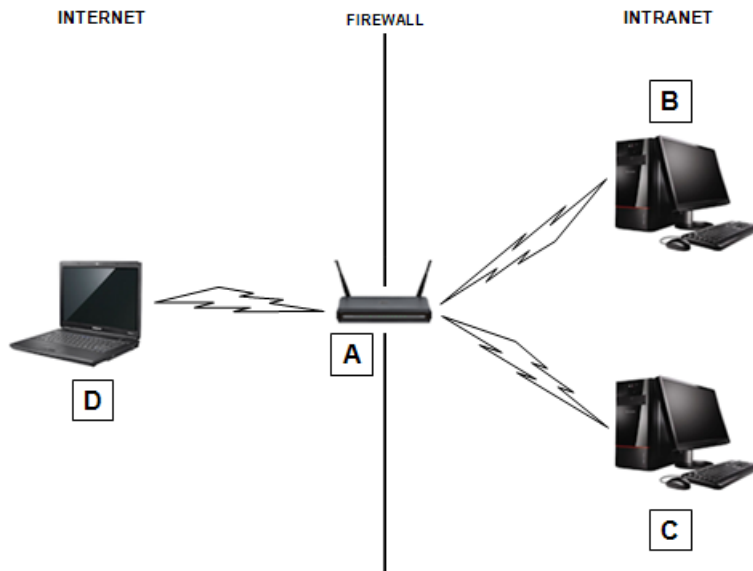

Configuring a router to forward network communications

In a typical home or small office environment, a router assigns a private network address to an internal computer. You should also be aware that *VNC Server* listens for network communications on a particular port. The router must be configured to forward communications from *VNC Viewer* to the correct port at the correct private network address. This procedure is known as port forwarding.

Note: Port forwarding instructions are specific to routers. If you do not have access to the host computer, ask a host computer user to consult the manufacturer's documentation, or visit www.portforward.com.

Note that a router may act as a public interface to more than one computer in a home or small office environment. If you want to connect to multiple host computers, then *VNC Server* must be running on each and listening on a different port. The router must be configured to distinguish between host computers using port numbers.

Consider the following example:

A. Router with a network address assigned by an ISP, for example 212.44.6.81. **B.** Host computer with a network address assigned by the router, for example 192.168.0.1. VNC Server is listening on the default port, 5900. **C.** Host computer with a network address assigned by the router, for example 192.168.0.2. VNC Server has been configured to listen on port 5901. **D.** Client computer running VNC Viewer.

In this scenario, the router must be configured to forward port 5900 to host computer B at 192.168.0.1 and port 5901 to host computer C at 192.168.0.2.

When you connect to either host computer from *VNC Viewer*, you must enter the network address of the router: 212.44.6.81. In addition, to connect to host computer C, you must qualify the router's network address with the port number: 212.44.6.81:1. To find out why this is, see *Qualifying a network address with a port number* on page 30.

Qualifying a network address with a port number

VNC Server listens for network communications on a particular *port*. By default, and providing it is available when *VNC Server* starts, this is port 5900 for connection requests. This port is registered for use by *VNC Server* with the Internet Assigned Numbers Authority (IANA).

Note: For more information on ports, see *Configuring ports on page 88*.

If *VNC Server* is listening on any other port, you must qualify the network address of the host computer (or router) with the port number when you connect from *VNC Viewer*, for example:

If you know that *VNC Server* is listening on a port between 5901 and 5999, append a colon (:) and an identifying number (1 through 99) to the network address, for example:

```
johndoe:1  
192.168.0.133:1  
[2001:db8::1]:1
```

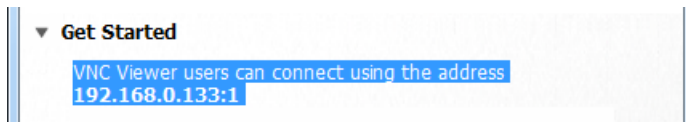

If you know that *VNC Server* is listening on any other port, append a double colon (::) and the full port number to the network address, for example:

```
johndoe::6001  
192.168.0.133::6001  
[2001:db8::1]::6001
```

If you do not know on which port *VNC Server* is listening:

- And you do not have access to the host computer, you will need to consult your system administrator or a host computer user.
- And you *do* have access to the host computer:
 - a. Open the **VNC Server** dialog. See *how to do this*.

- b. Examine the appropriate section of the **Get Started** section:

In this example, *VNC Server* is running on host computer 192.168.0.133 and listening on port 5901.

Allowing network communications through a firewall

If the host computer is protected by a firewall, then the firewall must be configured to allow incoming network communications to the port on which *VNC Server* is listening. To find out which port this is, see *Qualifying a network address with a port number* on page 30.

The firewall might be automatically configured by the operating system of the host computer. If not, you will probably see the following error message when you connect from *VNC Viewer*:

```
Connection timed out (10060)
```

The instructions for adding exceptions for ports are specific to firewalls. If you do not have access to the host computer, ask a host computer user to consult the manufacturer's documentation.

Miscellaneous connection messages

This section explains various error messages you might see.

Failing to authenticate correctly

If you see the following error message:

```
Either the username was not recognized, or the password was incorrect.
```

then you have not authenticated correctly to *VNC Server*. Note that user names and passwords are case-sensitive.

If you do not know the correct user name or password, and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to relax the authentication rules. For more information, see *Relaxing the authentication rules* on page 104.

Failing to authenticate as 'you'

If you see the following error message:

```
Access is denied.
```

then *VNC Server* has been configured to require the credentials of a host computer user. *Your* user name and password, however, have not been added to the authentication list.

If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to register your credentials. For more information, see *Managing users and groups in the authentication list* on page 102.

Connecting from an unauthorized computer

If you see the following error message:

```
The connection closed unexpectedly.
```

then it could be that *VNC Server* has been configured to prevent connections from the client computer you are using.

If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to unblock your client computer. For more information, see *Preventing connections from particular client computers* on page 111.

Alternatively, you may be able to connect from a different client computer.

Being rejected by a host computer user

If you see the following error message:

```
Connection rejected by host computer user.
```

then *VNC Server* has been configured to display connection prompts to a host computer user, and your request has either been explicitly rejected, or has timed out (this could either be because the prompt was deliberately ignored, or because no host computer user is actually present).

If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to bypass host computer connection prompts. For more information, see *Preventing particular users connecting* on page 113.

Using VNC Viewer

This chapter explains how to control a host computer to which you are connected using *VNC Viewer*, and how *VNC Viewer* features can enhance your productivity while the connection is in progress.

Restricting access to features	46

Starting VNC Viewer

To start *VNC Viewer* on a client computer, follow the instructions in *Step 2: Start VNC Viewer on the client computer* on page 21.

In most circumstances, *VNC Viewer* is ready to connect to *VNC Server* out-of-the-box. Carry on from *Connecting to a host computer* on page 37.

In some circumstances, you may need to configure *VNC Viewer* before you connect. For more information, see *Configuring VNC Viewer before you connect* on page 35.

To see how to start *VNC Viewer* so that it listens for a reverse connection, start with *Starting Listening VNC Viewer* on page 34.

Starting Listening VNC Viewer

You can start *VNC Viewer* in such a way that it does not connect to *VNC Server* but rather waits for *VNC Server* to connect to it. This is called a *reverse connection*. For more information about this feature, and why you might want to use it in conjunction with a host computer user, see *Establishing a reverse connection* on page 107.

Note: Reverse connections are not secure and should only be used in a locked-down environment.

To start *Listening VNC Viewer*, open a Command or Terminal window and:

- Under Windows, run the command `<VNC Viewer>.exe -listen.`
- Under UNIX/Linux, run the command `./<VNC Viewer> -listen.`
- Under Mac OS X, run the command `<VNC Viewer>.app/Contents/MacOS/vncviewer -listen.`

Note: If you installed *VNC* on the client computer, you can start *Listening VNC Viewer* from the menu system of most operating systems, which may be more convenient. See *Setting up the client computer* on page 12 for more information.

Under Windows and Mac OS X, a VNC Viewer icon  is displayed in the Notification area or Status bar.

Under Windows 7, note this area is hidden by default and accessible from  to the right of the Taskbar. Hover the mouse cursor over the icon to confirm that *Listening VNC Viewer* is running:

Under Windows and Mac OS X, the VNC Viewer icon has a shortcut menu:

You do not need to configure *Listening VNC Viewer*, but if you want to do so before a connection is established, select **Default Options**. For more information, start with *Configuring VNC Viewer before you connect* on page 35.

Note: Select **New Connection** to establish a connection to VNC Server in the normal way. Carry on from *Connecting to a host computer* on page 37.

If a reverse connection:

- Is successfully established, *Listening VNC Viewer* displays the host computer's desktop in a new window on the client computer in exactly the same way as VNC Viewer. Carry on from *The VNC Viewer user experience* on page 38.
- Is not successful, start with *Establishing a reverse connection* on page 107.

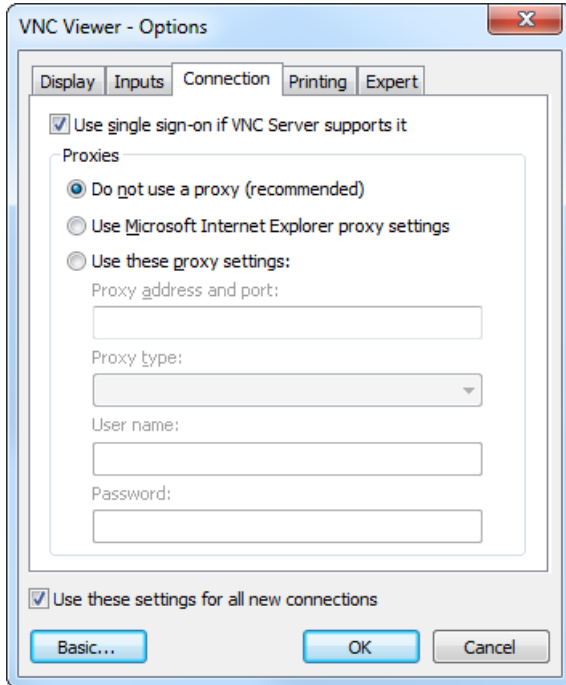

Configuring VNC Viewer before you connect

In most circumstances, VNC Viewer is ready to connect to VNC Server out-of-the-box. You do not need to configure it. Carry on from *Connecting to a host computer* on page 37.

However, you must configure VNC Viewer before you connect in the following circumstances:

- Your client computer is protected by a proxy server. See *Connecting via a proxy server* on page 36.
- VNC Server mandates the single sign-on authentication mechanism but you do not want to authenticate as the user you logged on to the *client* computer as. See *Disabling single sign-on* on page 36.
- You want to specify printing options. See *Configuring printing* on page 37.

To configure *VNC Viewer* before you connect, click the **Options** button at the bottom of the **VNC Viewer** dialog. *More on this dialog.* The **VNC Viewer - Options** dialog opens:

(In this picture, the dialog is in Advanced mode.)

Note that the **Connection** and **Printing** tabs are not available after you connect. *More on this dialog.*

Connecting via a proxy server

If your client computer is protected by a proxy server, you must tell *VNC Viewer* about that proxy server. On the **Connection** tab, choose:

- **Use Microsoft Internet Explorer proxy settings** if this browser has already been provisioned with proxy server information. Note this option has a different name under UNIX/Linux and Mac OS X.
- **Use these proxy settings** to specify the network address of either an HTTP or a SOCKS 5 proxy server, and a port on which an appropriate application or process is listening, separated by a colon.

If the proxy server is protected by BASIC or DIGEST authentication, enter a user name and password in the appropriate boxes.

Disabling single sign-on

Note: The information in this section applies to *VNC Viewer* for Windows and Mac OS X, for connections to *VNC Server (Enterprise)* only.

By default, if *VNC Server (Enterprise)* specifies single sign-on as its authentication mechanism, then you may be able to connect without supplying a user name and password. This is because you have already

successfully authenticated to a network when logging on to your client computer. For more information, see *Authenticating automatically using client computer user credentials* on page 105.

You can disable this feature if you want to connect to *VNC Server* using the credentials of a different user. This might give you access to more VNC features while the connection is in progress. To do this, turn off **Use single sign-on if VNC Server supports it** on the **Connection** tab.

Configuring printing

By default, when you connect to *VNC Server (Enterprise)* or *VNC Server (Personal)*, your client computer's default printer (if it has one) is shared with the host computer and made *its* default while the connection is in progress. This means you can print host computer files directly to your local printer. For more information about this feature, see *Printing host computer files to a local printer* on page 60.

You can print but choose not to change the host computer's default printer. This means you will have to explicitly select your printer when you print. To do this, turn off **Make it the default printer on VNC Server** on the **Printing** tab.

To disable printing, choose **Don't share a printer**.

Connecting to a host computer

This section summarizes how to connect from a client computer running *VNC Viewer* to a host computer running *VNC Server*. For a step-by-step guide, see *Chapter 2, Getting Connected* on page 19.

1. Start *VNC Viewer* on the client computer. The **VNC Viewer** dialog opens.
2. In the **VNC Server** dropdown, enter a private or a public network address for the host computer, qualified, if applicable, by the port number on which *VNC Server* is listening, for example `192.168.0.133:1`.
3. From the **Encryption** dropdown, select an encryption option, or retain the default: `Let VNC Server choose`.
4. Click the **Connect** button.

You may be asked to confirm a *VNC Server* signature, acknowledge the encryption status, and authenticate to *VNC Server*.

If the connection is successful, *VNC Viewer* displays the host computer's desktop in a new window on the client computer. Carry on from *The VNC Viewer user experience* on page 38. If the connection fails for any reason, start with *Troubleshooting connection* on page 26.

Note: Once connected, you can save a connection so you can quickly reconnect without having to remember the network address and authentication credentials. For more information, see *Appendix A, Saving Connections* on page 121.

The VNC Viewer user experience

The rest of this chapter assumes you are successfully connected to a host computer. If not, see *Connecting to a host computer* on page 37.

When a connection is established, *VNC Viewer* displays the host computer's desktop in a new window on the client computer:

A. Desktop of a client computer running Windows 7. **B.** VNC Viewer displaying the desktop of a host computer running Ubuntu 11.04 Linux.

Note: If the host computer is running UNIX/Linux, *VNC Viewer* may display a *virtual* desktop instead, in which case what you see is *not* the desktop visible to a host computer user. For more information on this feature, see *Running multiple instances of VNC Server* on page 78.

Note that other *VNC Viewer* users may be connected to the host computer and controlling it at the same time as you. In addition, a host computer user may be present. Operations may occur unexpectedly!

Controlling the host computer using your mouse

Your client computer's mouse is now shared with the host computer. This means that:

- Moving the mouse and clicking within the *VNC Viewer* window affects the host computer and not the client.
- Moving the mouse and clicking outside the *VNC Viewer* window, or on the *VNC Viewer* title bar or window buttons (**Minimize**, **Maximize**, and **Close**), affects the client computer and not the host.

Note: If your mouse has no effect on the host computer, it may have been disabled. For more information, see *Restricting access to features* on page 46.

If client and host computers have different numbers of mouse buttons, you can configure *VNC Viewer* to emulate those you do not have. See *Configuring your mouse* on page 45 for more information.

Controlling the host computer using your keyboard

Your client computer's keyboard is now shared with the host computer, with the exception of:

- The function key that opens the shortcut menu (F8 by default).
- The CTRL-ALT-DELETE key combination.

These commands are interpreted by the client computer. Alternative ways of sending them to the host computer are available; start with *Using the shortcut menu* on page 41 for more information. Under Windows, note you can choose for certain other keys or key combinations to be interpreted by your client computer rather than the host. See *Configuring your keyboard* on page 45 for more information.

Note: If your keyboard has no effect on the host computer, it may have been disabled. For more information, see *Restricting access to features* on page 46.

Note it is possible for client and host computers to have different types of keyboard. Not all the keys available to a host computer user may be available to you, and some keys with the same name may have different behavior. This is especially likely if you are connecting to Mac OS X from Windows or Linux with a PC keyboard, or *vice versa*; see www.realvnc.com/products/vnc/documentation/latest/misc/keyboard-mapping/.

Interacting with VNC Server

When you connect, a *VNC Server* icon  is displayed on the host computer's desktop, shaded black:

(Windows 7 client computer; Ubuntu 11.10 Linux host)

The *VNC Server* icon confirms that *VNC Server* is running on the host computer, provides information to help *VNC Viewer* users connect, confirms that at least one *VNC Viewer* user is connected (the icon changes color), and has a shortcut menu to perform useful operations. All this information and functionality is available to you as a connected user. For more information, see *Working with VNC Server* on page 81.

Note: Under UNIX/Linux, in some circumstances, the *VNC Server* icon is not shaded black. Under some versions, no *VNC Server* icon can be displayed. In the latter scenario, shortcut menu commands are available from the **More** button on the **VNC Server** dialog.

Note that the *VNC Server* icon also provides access to *VNC Server* options. However, you cannot configure *VNC Server* in Service Mode unless you know the credentials of a user with administrative privileges on the host computer (or are logged in as one). For more information, see *Using the VNC Server - Options dialog on page 88*.

Using the toolbar

VNC Viewer has a toolbar to facilitate common operations.

Note: If you cannot access the *VNC Viewer* toolbar, it may have been disabled. For more information, see *Changing appearance and behavior on page 44*.

The *VNC Viewer* toolbar is located at the top center of the *VNC Viewer* window. To use it, hover the mouse cursor over the hot area:

The following table explains the effect of clicking each toolbar button.

	Button	Purpose
	New Connection	Establish a new connection to the same host computer, or to a different one. See <i>Connecting to a host computer on page 37</i> .
	Save Connection	Save the current connection so you can quickly reconnect without having to remember the network address and authentication credentials. See <i>Appendix A, Saving Connections on page 121</i> .
	Close Connection	Close the current connection (and the <i>VNC Viewer</i> window).
	Options	Configure most aspects of <i>VNC Viewer</i> while the current connection is in progress. See <i>Using the VNC Viewer - Options dialog on page 42</i> . Note that some options must be configured before you connect. See <i>Configuring VNC Viewer before you connect on page 35</i> .
	Full Screen Mode	Toggle full screen mode on and off.
	Send Ctrl-Alt-Del	Send the CTRL-ALT-DELETE command to the host computer. (Pressing this key combination will be interpreted by the client computer.) You could alternatively press SHIFT-CTRL-ALT-DELETE.
	File Transfer	Browse to the location of client computer files to send to the host computer. See <i>Transferring files between client and host computers on page 62</i> .

	Button	Purpose
	Start Chat Session	Chat with other <i>VNC Viewer</i> users connected to the same host computer, or with a host computer user. See <i>Communicating securely using chat</i> on page 67.
	Connection Information	Display technical information about the current connection, such as the encryption method and compression format. You may need this if you contact Technical Support.
	<i>connection speed</i>	Hover over to reveal the current connection speed. For more information on performance, see <i>Changing appearance and behavior</i> on page 44.

Using the shortcut menu

VNC Viewer has a shortcut menu that facilitates many of the same common operations as the *VNC Viewer* toolbar. *More on this toolbar.*

Note: If you cannot access the *VNC Viewer* shortcut menu, it may have been disabled. For more information, see *Changing appearance and behavior* on page 44.

By default, to open the shortcut menu, press the F8 key (you may need to hold down the FN key on some PC laptops or Mac OS X computers):

(Some standard Windows menu options have been omitted from this example.)

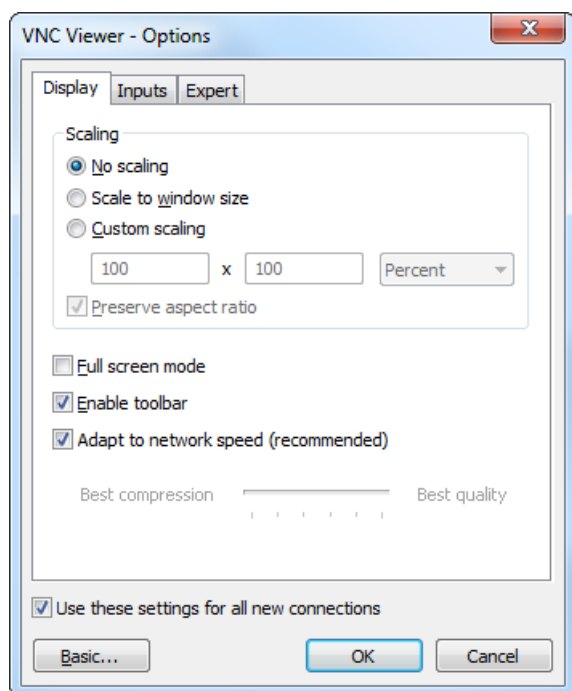

Note: Under Mac OS X, more **Send <key>** options are available to send Mac-specific commands to a host computer also running Mac OS X.

The following table explains the effect of selecting shortcut menu options that do not have equivalent toolbar buttons.

Option	Purpose
Relative Pointer Motion	Turn on if the host computer's mouse cursor appears to be behaving abnormally, for example by accelerating too fast.
Send F8	Send an F8 command to the host computer. (By default, F8 opens the shortcut menu; see <i>Changing the shortcut menu key</i> on page 46 for how to choose a different key.)
Ctrl key	Turn on to simulate holding down the CTRL key.
Alt key	Turn on to simulate holding down the ALT key.
Refresh Screen	Refresh the display of the host computer's desktop.
About VNC Viewer	Display version information. You may need this if you contact Technical Support.

Using the VNC Viewer - Options dialog

The **VNC Viewer - Options** dialog allows you to configure *VNC Viewer* while a connection is in progress:

(In this picture, the dialog is in Advanced mode.)

Note: Some VNC Viewer options must be configured *before* you connect. For more information, see *Configuring VNC Viewer before you connect* on page 35.

To open the **VNC Viewer - Options** dialog, click the **Options**  toolbar button, or select **Options** from the shortcut menu. (If the *VNC Viewer* toolbar or shortcut menu are not accessible, see *Changing appearance and behavior* on page 44.)

The first time you open this dialog, it opens in Basic mode, and only one tab is available, containing the most common options. Click the **Advanced** button in the bottom left corner to switch to Advanced mode and see all the tabs in the example above. Note that the **Expert** tab is recommended for expert users only.

By default, any changes you make apply both to the current connection *and to all future connections to any host computer*. To apply changes just to the current connection, turn off **Use these settings for all new connections** first.

Many of the options in this dialog are explained in the remainder of this chapter.

Managing the current connection

You can manage aspects of the current connection while it is in progress.

Note: Most of the operations described in this section are facilitated by the *VNC Viewer* toolbar. *More on this toolbar.*

Saving the current connection

You can save the current connection so you can quickly reconnect without having to remember the network address and authentication credentials. In addition, your preferred *VNC Viewer* environment for controlling the host computer is automatically recreated each time.

To save the current connection, click the **Save Connection**  toolbar button. Carry on from *Appendix A, Saving Connections* on page 121.

Establishing a new connection

You can establish a new connection to the same host computer, or to a different one.

To do this, click the **New Connection**  toolbar button. The **VNC Viewer** dialog opens. Carry on from *Connecting to a host computer* on page 37.

By default, any options you configure are inherited by the new connection. To prevent this, open the **VNC Viewer - Options** dialog and turn off **Use these settings for all new connections** first. *More on this dialog.*

Closing the current connection

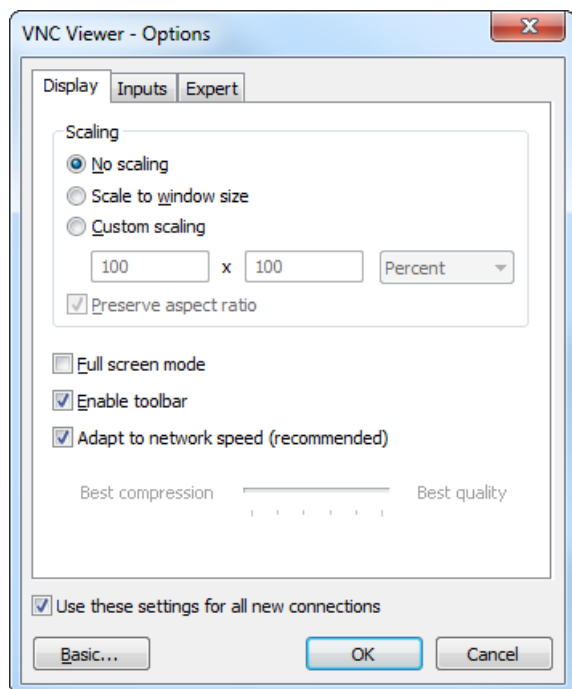

You can quickly close the current connection. To do this, click the **Close Connection**  toolbar button. You are prompted to confirm the operation before the *VNC Viewer* window closes.

Changing appearance and behavior

By default, when a connection is established:

- *VNC Viewer* does not scale the host computer's desktop. Instead, scroll bars are added to the window if the desktop is too large.
- The *VNC Viewer* window is set to a particular size.
- *VNC Viewer* displays the host computer's desktop in a color quality appropriate to the network connection speed.
- Your mouse and keyboard are set to interact with the client and host computers in particular ways.
- The *VNC Viewer* toolbar is accessible (from the top center hot area).
- The *VNC Viewer* shortcut menu is accessible (by pressing F8).

You can change these defaults by configuring options on the **Display** tab of the **VNC Viewer - Options** dialog. *More on this dialog.*

Scaling the host computer's desktop

You can scale the host computer's desktop, which might make it easier to navigate and to use.

To scale the desktop to the size of the *VNC Viewer* window, choose **Scale to window size**.

To scale the desktop to a custom size, choose **Custom scaling**, and specify a width and height. Turn on **Preserve aspect ratio** to automatically calculate a height for a given width, and *vice versa*. Note that the *VNC Viewer* window inherits these dimensions and cannot be made bigger using the mouse (only smaller).

Changing the size of the VNC Viewer window

You can use the mouse to resize the *VNC Viewer* window in the expected way for the platform of the client computer. The window's Application buttons (**Minimize**, **Maximize**, and **Close**) also work in the expected way.

To toggle full screen mode on and off, click the **Full Screen Mode**  toolbar button. Note scroll bars are not displayed in this mode; bump the mouse against an edge to scroll.

Trading performance for picture quality

You may be able to enhance the performance of the connection by reducing the number of colors used to display the host computer's desktop. To do this, turn off **Adapt to network speed**, and move the slider towards **Best compression**.

Conversely, you may be able to improve the picture quality by increasing the number of colors. To do this, move the slider towards **Best quality**. Note that sending more pixel information across the network may have an adverse effect on performance.

Configuring your mouse

Note: The information in this section applies to *VNC Viewer* for Windows and Mac OS X only.

You can emulate buttons missing because your mouse has fewer buttons than the host computer's mouse.

For example, if your mouse only has two buttons, turn on **Enable 3-button mouse emulation**. To emulate the missing middle button, click the left and right mouse buttons simultaneously. Under Mac OS X, if your mouse only has one button, you can also, or alternatively, turn on **Enable 2-button mouse emulation**. To emulate the missing right button, hold down the CTRL key and press the button.

Note these options are on the **Inputs** tab.

Configuring your keyboard

Note: The information in this section applies to *VNC Viewer* for Windows only.

By default, and with the exception of CTRL-ALT-DELETE and the function key used to open the shortcut menu, key presses affect the host computer and not the client. To reverse this behavior for the application-level keys listed below, turn off **Pass special keys directly to VNC Server**. Note this option is on the **Inputs** tab.

Affected keys/combinations: WINDOWS (also known as START), PRINT SCREEN, ALT-TAB, ALT-ESCAPE, CTRL-ESCAPE.

Disabling the toolbar

You can disable the *VNC Viewer* toolbar. *More on this toolbar.* To do this, turn off **Enable toolbar**.

Note that if you disable the *VNC Viewer* shortcut menu as well you will not be able to access the *VNC Viewer* toolbar again while the current connection is in progress.

Disabling the shortcut menu

You can disable the *VNC Viewer* shortcut menu. *More on this menu.* To do this, select `none` from the **Menu key** dropdown. Note this option is on the **Inputs** tab.

Note that if you disable the *VNC Viewer* toolbar as well you will not be able to access the *VNC Viewer* shortcut menu again while the current connection is in progress.

Changing the shortcut menu key

You can change the function key used to open the shortcut menu. To do this, select a function key from the **Menu key** dropdown. Note this option is on the **Inputs** tab. The shortcut menu updates to reflect the fact that you can no longer press the chosen key to send a command to the host computer.

Restricting access to features

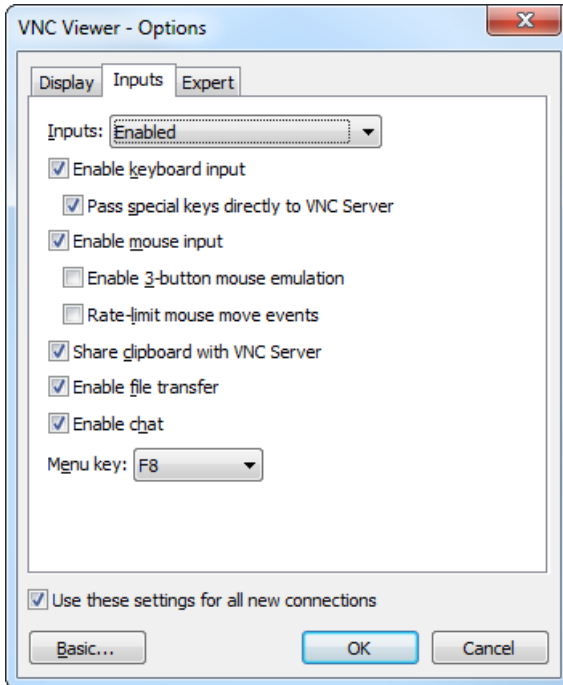

By default, while a connection is in progress, you can control the host computer using your keyboard and mouse, and in addition copy and paste text between applications running on the client and host computers.

For connections to *VNC Server (Enterprise)* and *VNC Server (Personal)*, you can also:

- Print host computer files directly to a local printer.
- Exchange files with the host computer.
- Chat with other *VNC Viewer* users connected to the same host computer, or with a host computer user.

Note: *VNC Server* may have been configured to prevent some or all of these features. For more information, see *Restricting functionality for connected users on page 93*. In addition, *VNC Viewer* might have been configured to disable printing before the connection started.

You can restrict access to features while the connection is in progress by configuring options on the **Inputs** tab of the **VNC Viewer - Options** dialog. *More on this dialog.* You might want to do this if you are watching a demonstration on the host computer, for example, and want to prevent inadvertent interruption.

Note: You can enable features again at any time. To prevent this for the current connection only, disable the VNC Viewer toolbar and shortcut menu. For more information, see *Changing appearance and behavior* on page 44.

Making VNC Viewer ‘view only’

You can quickly prevent all interchange with the host computer, making VNC Viewer ‘view only’. To do this, select **Disabled** (view-only mode) from the **Inputs** dropdown.

Disabling your keyboard

You can disable the client computer’s keyboard. To do this, turn off **Enable keyboard input**.

Disabling your mouse

You can disable the client computer’s mouse. To do this, turn off **Enable mouse input**.

Disabling file transfer

You can disable file transfer between client and host computers. To do this, turn off **Enable file transfer**.

For more information about this feature, see *Transferring files between client and host computers on page 62*.

Disabling copy and paste text

You can disable copy and paste text between applications running on the client and host computers. To do this, turn off **Share clipboard with VNC Server**.

For more information about this feature, see *Copying and pasting text between client and host computers on page 66*.

Disabling chat

You can disable chat. To do this, turn off **Enable chat**. For more information about this feature, see *Communicating securely using chat on page 67*.

4

Connecting From A Web Browser

This chapter explains how to connect to and control a host computer using *VNC Viewer for Java*. All you need to do this is a Java-enabled web browser to download *VNC Viewer for Java* from *VNC Server (Enterprise)* or *VNC Server (Personal)* on demand; you do not have to install any software. This may be useful if you are at an Internet café, for example.

Note: You cannot download *VNC Viewer for Java* from *VNC Server (Free)*.

Once downloaded, you can use the *VNC Viewer for Java* applet to establish a connection in exactly the same way as *VNC Viewer*. You use your mouse and keyboard to control the host computer exactly as you would using *VNC Viewer*.

Note: *VNC Viewer for Java* has considerably fewer remote control features than *VNC Viewer*. For more information, see *Connecting from VNC Viewer for Java* on page 15.

Contents

Connecting to a host computer	50
The VNC Viewer for Java user experience	54
Working with VNC Viewer for Java	55

Connecting to a host computer

Connecting to a host computer is a two-stage process using *VNC Viewer for Java*:

1. Download *VNC Viewer for Java* from *VNC Server (Enterprise)* or *VNC Server (Personal)* running on the host computer you want to connect to. See *Downloading VNC Viewer for Java* on page 50.
2. Use the *VNC Viewer for Java* applet to connect to *VNC Server*. See *Connecting to VNC Server* on page 52.

Downloading VNC Viewer for Java

The first stage is to download *VNC Viewer for Java* to your web browser on demand. To do this:

1. Start a Java-enabled web browser on the client computer, for example the latest version of Internet Explorer, Firefox, Safari, or Chrome.

Note: For more information on Java, visit www.java.com. Note that Java (JRE or JDK) 5+ must be installed on the client computer.

2. In the address bar, enter `http://` and the network address of the host computer, qualified by the port number on which *VNC Server* is listening for download requests, for example `http://192.168.0.133:5800`.

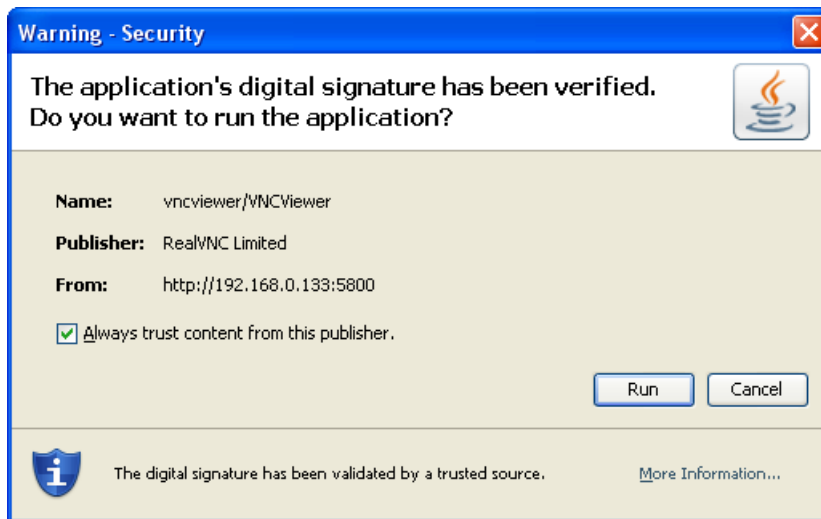

If you do not know a network address for the host computer and you do not have access to it, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and you are connecting within a private network, the information you need is displayed in the **Get Started** section of the **VNC Server** dialog. *More on this dialog.*

Note: If you are connecting over the Internet, you will probably need to enter the network address of a router instead. See *Connecting over the Internet* on page 28 for more information.

By default, *VNC Server* listens for download requests on port 5800. If the download request fails, it may be because *VNC Server* is listening on a different port; see *Qualifying a network address with a port number* on page 30 for more information. A download request may also fail if the host computer is protected by a router and/or a firewall and these devices have not been configured to allow access to *VNC Server* at the correct port. For more information on this, and connection issues in general, see *Troubleshooting connection* on page 26.

3. If this is the first time you have *VNC Viewer for Java*, you are prompted to trust it:

You can do this in complete confidence. However, you can choose *not* to trust *VNC Viewer for Java* and still connect, though note you cannot copy and paste text between applications in the normal way.

In the example above, click the **Run** button to trust *VNC Viewer for Java*, and **Cancel** to continue connecting without trusting it.

If *VNC Viewer for Java* successfully downloads, the **VNC Viewer** dialog opens:

(In this picture, the web browser is Firefox 8. Note that the web browser window must stay open while the connection is in progress.)

Connecting to VNC Server

The second stage is to use *VNC Viewer for Java* to connect to *VNC Server*. This is the same process as connecting from *VNC Viewer*.

The **VNC Server** dropdown on the **VNC Viewer** dialog displays the network address of the host computer, qualified by the port number on which *VNC Server* is listening for connection requests (in the example below, the digit 0 corresponds to the default port, 5900):

For more information on network addresses and port numbers, start with *Step 3: Identify VNC Server running on the host computer* on page 21.

To continue connecting:

1. From the **Encryption** dropdown, select an encryption option, or retain the default: *Let VNC Server choose*. For more information on this, see *Step 4: Request an encrypted connection* on page 22.
2. If you want to configure *VNC Viewer for Java* before you connect, click the **Options** button. For information on why you might want to do this, see *Configuring VNC Viewer for Java before you connect* on page 53.
3. Click the **Connect** button.

You may be asked to confirm a signature that uniquely identifies *VNC Server*, acknowledge the encryption status, and to authenticate. For more information on these issues, see *Step 5: Connect to VNC Server* on page 23.

If the connection is successful, *VNC Viewer for Java* displays the host computer's desktop in a new window on the client computer. Carry on from *The VNC Viewer for Java user experience* on page 54.

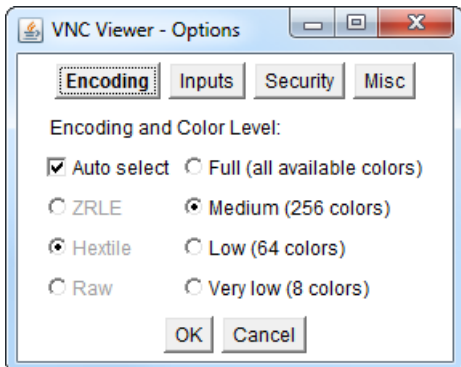

If the connection fails for any reason, start with *Troubleshooting connection* on page 26.

Configuring VNC Viewer for Java before you connect

VNC Viewer for Java is ready to connect to *VNC Server* and control a host computer out-of-the-box. You do not need to configure it. However, you can change some aspects to suit your requirements and environment if you wish.

Some options must be configured before you connect. Most, however, can be configured once you are connected, and changes applied to the current connection. For more information, see *Using the VNC Viewer - Options dialog* on page 56.

To configure *VNC Viewer for Java* before you connect, click the **Options** button in the **VNC Viewer** dialog. The **VNC Viewer - Options** dialog opens:

The following options must be configured before a connection is made:

- To make the connection more secure, choose an alternative to the default key length of **512 bits**. This option is on the **Security** tab.
- To ensure your privacy at the start of the connection, turn off **Shared (don't disconnect other VNC Viewers)** in order to disconnect other users. This option is on the **Misc** tab.

The VNC Viewer for Java user experience

When a connection is established, *VNC Viewer for Java* displays the host computer's desktop in a new window on the client computer:

A. Desktop of a client computer running Windows 7. **B.** Java-enabled web browser. This window must stay open while the connection is in progress. **C.** VNC Viewer for Java displaying the desktop of a host computer running Ubuntu 11.04 Linux.

The client computer's mouse and keyboard are now shared with the host computer in exactly the same way as VNC Viewer. For more information, start with *Controlling the host computer using your mouse* on page 39.

Working with VNC Viewer for Java

You can use *VNC Viewer for Java* to:

- Control the host computer using your keyboard and mouse.
- Copy and paste text between applications running on the client and host computers.
- Trade performance for picture quality while the connection is in progress.
- Restrict access to functionality while the connection is in progress.

See the sections below for more information on these issues. For a summary of functionality that is *not* available, see *Connecting from VNC Viewer for Java* on page 15.

Using the VNC Viewer for Java shortcut menu

VNC Viewer for Java has a shortcut menu to facilitate common operations.

Note: *VNC Viewer for Java* does not have a toolbar.

To open the shortcut menu, press the F8 key (you may need to hold down the FN key under Mac OS X):

Exit VNC Viewer
Clipboard...
Send F8
Send Ctrl-Alt-Del
Refresh screen
New connection...
Options...
Connection info...
About VNC Viewer...
Dismiss menu

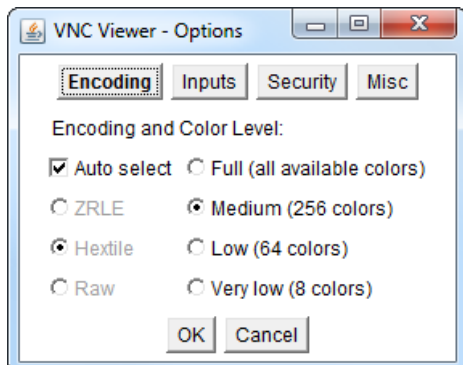

The following table explains the effect of selecting these menu options.

Option	Purpose
Exit VNC Viewer	Close the current connection (and the <i>VNC Viewer for Java</i> window).
Clipboard	Preview the contents of the Clipboard and, providing copy and paste is enabled, paste it to an application running either on the client or on the host computer. See <i>Copying and pasting text</i> on page 57. Note that if you chose not to trust <i>VNC Viewer for Java</i> when you downloaded it, you can only copy and paste text between the two computers via this dialog.
Send F8	Send an F8 command to the host computer. (F8 opens the shortcut menu.)
Send Ctrl-Alt-Del	Send the CTRL-ALT-DELETE command to the host computer. (Pressing this key combination would be interpreted by the client computer.)

Option	Purpose
Refresh screen	Refresh the display of the host computer's desktop.
New connection	Start a new connection to the same host computer, or to a different one, using the same web browser session. You do not need to download <i>VNC Viewer for Java</i> again.
Options	Configure most aspects of <i>VNC Viewer for Java</i> while the current connection is in progress. See <i>Using the VNC Viewer - Options dialog</i> on page 56. Note that some options must be configured before you connect. See <i>Configuring VNC Viewer for Java before you connect</i> on page 53.
Connection info	Display technical information about the current connection, such as the encryption method and compression format. You may need this if you contact Technical Support.
About VNC Viewer	Display information about <i>VNC Viewer for Java</i> . You may need this if you contact Technical Support.
Dismiss menu	Close the shortcut menu.

Using the VNC Viewer - Options dialog

The **VNC Viewer - Options** dialog enables you to configure *VNC Viewer for Java* while the current connection is in progress:

Note: Some *VNC Viewer for Java* options must be configured *before* you connect. For more information, see *Configuring VNC Viewer for Java before you connect* on page 53.

To open the **VNC Viewer - Options** dialog, select **Options** from the shortcut menu. *More on this menu.*

The following sections explain the options in this dialog.

Trading performance for picture quality

You may be able to enhance the performance of *VNC Viewer for Java* by reducing the number of colors used to display the host computer's desktop. To do this, turn off **Auto select** and choose either 256, 64, or 8 colors. These options are on the **Encoding** tab.

You can also choose an alternative to the default **ZRLE** encoding. The **Hextile** and **Raw** encodings require increasingly less processing power to display the host computer's desktop, though note they also require progressively more bandwidth.

Restricting access to functionality

You can quickly prevent all interchange with the host computer, making *VNC Viewer for Java* 'view only'. To do this, turn on **View only (ignore mouse & keyboard)**. This option is on the **Inputs** tab.

You can disable copy and paste, or just copy and paste in a particular direction. For more information, see *Copying and pasting text* on page 57.

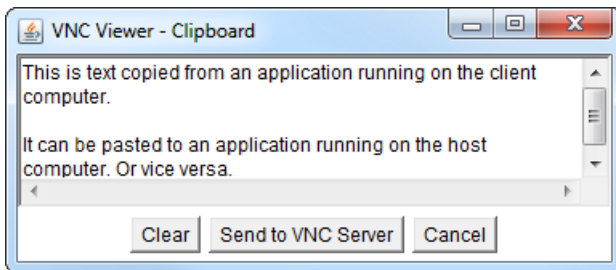

Troubleshooting display

If the mouse cursor is not behaving in the expected way, turn off **Render cursor locally**. If the screen is not updating properly, turn off **Fast CopyRect**. These options are on the **Misc** tab.

Copying and pasting text

You can copy and paste text between applications running on the client and host computers. This feature works in the same way as it does for *VNC Viewer*. See *Copying and pasting text between client and host computers* on page 66 for more information.

You can preview the contents of the Clipboard to see what text is available to paste. To do this, select **Clipboard** from the *VNC Viewer for Java* shortcut menu. *More on this menu*. The **VNC Viewer - Clipboard** dialog opens:

Disabling and enabling copy and paste

You can disable copy and paste while the current connection is in progress. To do this, open the **VNC Viewer - Options** dialog. *More on this dialog*. On the **Inputs** tab, turn off **Accept clipboard from VNC Server** and **Send clipboard to VNC Server**.

Note you can turn these options off separately in order to disable copy and paste in one direction only.

5

Exchanging Information

This chapter explains how to use *VNC Viewer* to exchange information with the host computer, or with other *VNC Viewer* users connected at the same time as you.

Note: Not all features are available for connections to *VNC Server (Free)*. For a summary, see *Connecting to VNC* on page 13.

Contents

Printing host computer files to a local printer	60
Transferring files between client and host computers	62
Copying and pasting text between client and host computers	66
Communicating securely using chat	67

Printing host computer files to a local printer

If you are connected to *VNC Server (Enterprise)* or *VNC Server (Personal)*, you can print host computer files directly to the default printer attached to your client computer (that is, to a *local* printer).

A. Local printer. **B.** Client computer running VNC Viewer. Printer A must be the client's default printer. **C.** Host computer running VNC Server, and storing the files to print.

Note: To see how to make a printer the client computer's default, consult its operating system documentation.

This powerful feature is ready to use out-of-the-box. Open a host computer file in the *VNC Viewer* window and print in the expected way for the application, for example by selecting **File > Print**. The local printer is automatically shared with the host computer and made *its* default while the connection is in progress, so the correct device should already be selected. Your request is added to the printer's queue and executed in turn.

A best possible quality print finish is attempted. This may mean the contents of the file are scaled to fit the dimensions of the local printer's paper. If the results are unexpected, see *Manipulating the quality of the print finish* on page 60.

If the host computer file does not print to the local printer, start with *Troubleshooting printing* on page 61.

Disabling and enabling printing

You can disable printing providing you do so before you connect. Open the **VNC Viewer - Options** dialog and, on the **Printing** tab, choose **Don't share a printer**. *More on this dialog.*

You can still print but choose not to change the host computer's default printer. To do this, turn off **Make it the default printer on VNC Server**. This means you will have to explicitly select the local printer when you print. The local printer will have a name of the form `<printer name> via VNC from <client computer name>`, for example `HP Color LaserJet CP2020 via VNC from Neptune`.

Manipulating the quality of the print finish

The quality of the print finish is determined by the characteristics of the local printer. For example, if the host computer file is a color photo but the local printer only prints in black and white, then color will be lost.

You may be able to configure printer options in order to achieve a better quality print finish. You should do this before you connect in the way expected for the operating system of the client computer, for example by selecting **Control Panel > Devices and Printers** under Windows 7.

If you are already connected, then you may be able to configure some printing preferences for the application you are printing from. This may include rotating pages, changing the page order, choosing a

number of pages per sheet, and advanced options such as changing the resolution or paper size. For more information, consult the application's documentation.

Troubleshooting printing

Printing host computer files to a local printer should work out-of-the-box. If it does not, check the following:

1. Are you connected to *VNC Server (Enterprise)* or *VNC Server (Personal)*? You cannot print *VNC Server (Free)* files. For more information, see *Connecting to VNC* on page 13.
2. If you are using a previous version of *VNC Viewer* or *VNC Server*, is it at least version 4.5? Printing is not supported by earlier versions.
3. Are both client and host computers running supported operating systems? Printing is not supported to or from certain platforms, including HP-UX, AIX, and Windows NT 4; in addition, prior configuration is required in order to print to or from Solaris 9 and 10, SUSE Linux, and systems with SE Linux enabled. For the latest information, visit www.realvnc.com/products/vnc/documentation/latest/misc/printing/.
4. If the host computer is running Linux or Mac OS X, is CUPS version 1.3 or later installed? For more information, consult the host computer's operating system documentation.
5. Is the local printer connected to the client computer? Is it switched on? Is it ready to print? Does it have paper? Is it set as the client computer's default printer?
6. Has *VNC Viewer* been configured to disable printing? To see how to enable it again, read *Disabling and enabling printing* on page 60. You will have to close the current connection and then reconnect.
7. Has *VNC Viewer* been configured to prevent the local printer becoming the host computer's default, which means it is not automatically selected? The request may have been sent to the wrong printer. To see how to make the local printer the host computer's default so it is always selected, read *Disabling and enabling printing* on page 60. You will have to close the current connection and then reconnect.

Note that if another *VNC Viewer* user connected to the same host computer before you, then *their* local printer becomes the host computer's default. You cannot change this. You must always explicitly select your local printer when you print.

If you have to explicitly select your local printer, note it will have a name of the form `<printer name>` via VNC from `<client computer name>`, for example HP Color LaserJet CP2020 via VNC from Neptune.

8. Has *VNC Server* been configured to prevent printing? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. For more information, see *Preventing printing on page 94*.
9. Has *VNC Server* been configured to prevent *you* printing? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. Alternatively, you may be able to connect as a different host computer user and use this feature. For more information, see *Restricting features for particular connected users* on page 114.
10. Has the host computer been configured to prevent printing system-wide? If this is the case and you do not have access to it, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure both it and *VNC Server*, you may be able to allow it again. For more information, see *Preventing printing on page 94*.

Transferring files between client and host computers

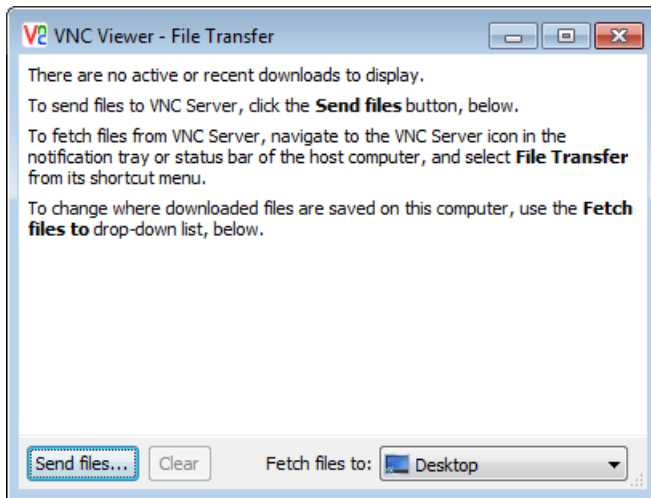

If you are connected to *VNC Server (Enterprise)* or *VNC Server (Personal)*, you can exchange files with the host computer.

Note: If file transfer fails for any reason, see *Troubleshooting file transfer* on page 65.

Sending files to a host computer

To send files to a host computer:

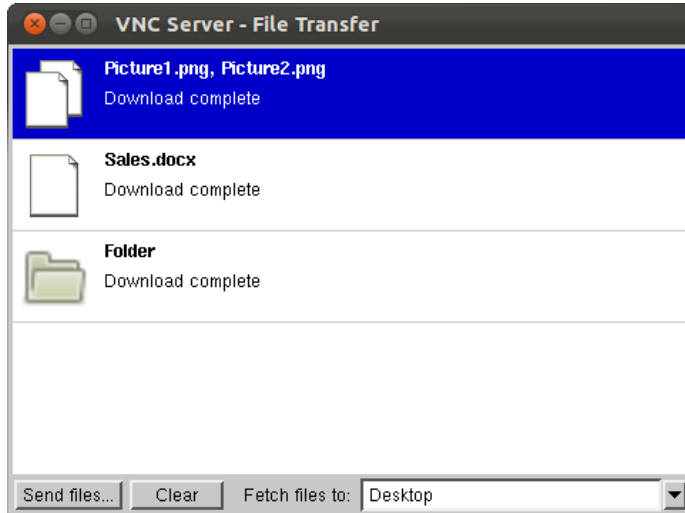

1. Click the **File Transfer**  *VNC Viewer* toolbar button. The **VNC Viewer - File Transfer** dialog opens on the client computer:

2. Click the **Send files** button. The **VNC Viewer - Send Files** dialog opens.
3. Select a file or folder. To select multiple files and/or folders, hold down the SHIFT key.

Note: Under Windows, you cannot directly select a folder. Instead, double-click to open that folder, then click **Use Entire Folder**. To select multiple folders, open the *parent* folder and click **Use Entire Folder**. Note this means other files and folders in the parent folder will also be transferred.

4. Click **Open** (**OK** under UNIX/Linux). The **VNC Server - File Transfer** dialog opens on the host computer:

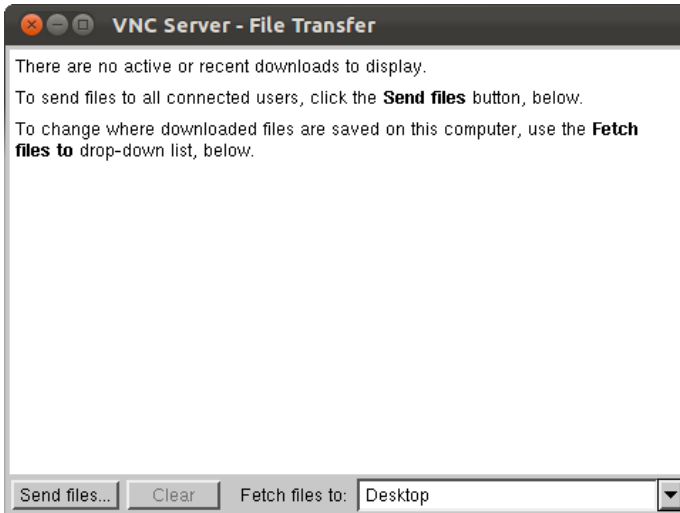

The most recent file transfer operation is highlighted. You can check its status, or pause or stop the transfer if it takes more than a few seconds.

By default, files are downloaded to the host computer's desktop (`Downloads` folder under Mac OS X). To change this for future file transfer operations, select an option from the **Fetch files to** dropdown at the bottom of the **VNC Server - File Transfer** dialog. Note you must have write permissions for the folder you choose. Alternatively, you can ask to be prompted each time.

Publishing files to all connected client computers

You can fetch files from a host computer. Note that all other *VNC Viewer* users connected at the same time as you will also receive the files. To do this:

1. In the *VNC Viewer* window, right-click the *VNC Server* icon  (typically shaded black) and, from the shortcut menu, select **File Transfer**. *More on this icon*. The **VNC Server - File Transfer** dialog opens on the host computer:

2. Click the **Send files** button. The **VNC Server - Send Files** dialog opens.
3. Select a file or folder. To select multiple files and/or folders, hold down the SHIFT key.

Note: Under Windows, you cannot directly select a folder. Instead, double-click to open that folder, then click **Use Entire Folder**. To select multiple folders, open the *parent* folder and click **Use Entire Folder**. Note this means other files and/or folders in the parent folder will also be transferred.

4. Click **Open** (**OK** under UNIX/Linux). The **VNC Viewer - File Transfer** dialog opens on the client computer:

The most recent file transfer operation is highlighted. You can check its status, or pause or stop the transfer if it takes more than a few seconds.

By default, files are downloaded to the client computer's desktop (Downloads folder under Mac OS X). To change this for future file transfer operations, select an option from the **Fetch files to** dropdown at the bottom of the **VNC Viewer - File Transfer** dialog. Note you must have write permissions for the folder you choose. Alternatively, you can ask to be prompted each time.

Disabling and enabling file transfer

You can disable file transfer while the current connection is in progress.

To do this, open the **VNC Viewer - Options** dialog and, on the **Inputs** tab, turn off **Enable file transfer**.

More on this dialog. The **File Transfer**  **VNC Viewer** toolbar button is disabled.

You can enable file transfer again at any time.

Troubleshooting file transfer

If file transfer does not work, check the following:

1. Are you connected to *VNC Server (Enterprise)* or *VNC Server (Personal)*? You cannot transfer files to or from *VNC Server (Free)*. For more information, see *Connecting to VNC* on page 13.
2. If you are using a previous version of *VNC Viewer* or *VNC Server*, is it at least version 4.4? File transfer is not supported by earlier versions.
3. Has *VNC Viewer* been configured to disable file transfer? To see how to enable it again, read *Disabling and enabling file transfer* on page 65.
4. Has *VNC Server* been configured to prevent file transfer? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you

do have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. For more information, see *Preventing file transfer* on page 94.

5. Has *VNC Server* been configured to prevent *you* transferring files? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. Alternatively, you may be able to connect as a different host computer user and use this feature. For more information, see *Restricting features for particular connected users* on page 114.

Copying and pasting text between client and host computers

You can copy and paste text between applications running on the client and host computers.

Note: The computer you are pasting to must support the language of the copied text in order for it to be pasted meaningfully. In addition, any formatting applied to the copied text, such as italics, will be lost.

To copy and paste text from an application on the client computer to one on the host:

1. On the client computer, copy the text in the expected way for the platform of the client computer, for example by selecting it and pressing `Ctrl-C` (`Cmd-C` on Mac OS X). The text is copied to the Clipboard.
2. Give the *VNC Viewer* window focus, open the destination application on the host computer, and paste the text in the expected way for the host's platform, for example by pressing `Ctrl-V`. (To emulate `Cmd-V` for a Mac OS X host computer, press `Alt-V` on a PC keyboard.)

You can copy and paste text from an application on the host computer to one on the client. Note that text copied can also be pasted by all other users connected at the same time as you. To do this:

1. Within the *VNC Viewer* window, copy the text in the expected way for the platform of the host computer, for example by selecting it and pressing `Ctrl-C`. (To emulate `Cmd-C` for a Mac OS X host computer, press `Alt-C` on a PC keyboard.) The text is copied to the Clipboard.
2. Give the destination application on the client computer focus, and paste the text in the expected way for the client's platform, for example by pressing `Ctrl-V` (`Cmd-V` on Mac OS X).

If copy and paste text fails for any reason, start with *Troubleshooting copy and paste text* on page 67.

Disabling and enabling copy and paste text

You can disable copy and paste text while the current connection is in progress.

To do this, open the **VNC Viewer - Options** dialog and, on the **Inputs** tab, turn off **Share clipboard with VNC Server**. *More on this dialog.*

You can enable copy and paste text again at any time.

Troubleshooting copy and paste text

If copy and paste text does not work, check the following:

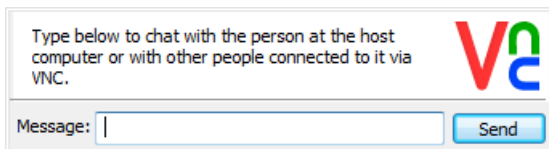

1. Has *VNC Viewer* been configured to disable copy and paste text? To see how to enable it again, read *Disabling and enabling copy and paste text* on page 66.
2. Has *VNC Server* been configured to prevent copy and paste text? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. For more information, see *Preventing copy and paste text* on page 94.
3. Has *VNC Server* been configured to prevent *you* copying and pasting text? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. Alternatively, you may be able to connect as a different host computer user and use this feature. For more information, see *Restricting features for particular connected users* on page 114.
4. Does the amount of text being copied and pasted exceed 256kB? If so, the entire paste operation fails, and the last text copied to the Clipboard is pasted instead.

Communicating securely using chat

If you are connected to *VNC Server (Enterprise)* or *VNC Server (Personal)*, you can chat with other *VNC Viewer* users connected to a host computer at the same time as you, and also with a host computer user if one is present.

Note: If you cannot use chat for any reason, see *Troubleshooting chat* on page 69.

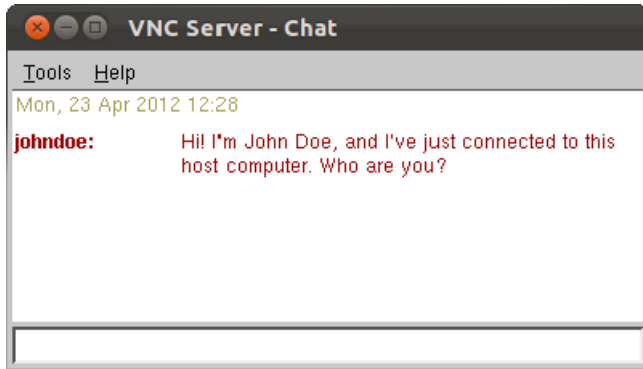

To participate in a conversation, or start a new one, click the **Start Chat Session**  *VNC Viewer* toolbar button. A message box appears at the bottom of the *VNC Viewer* window:

Type below to chat with the person at the host computer or with other people connected to it via VNC.

Message:

Enter a message and click the **Send** button. The message is broadcast to a **VNC Server - Chat** dialog that opens on the host computer, visible to you and to all other connected users (including a host computer user, if present):

Note: You are identified by the user name with which you authenticated to *VNC Server*, or as *VNC Viewer* if you did not enter a user name to connect.

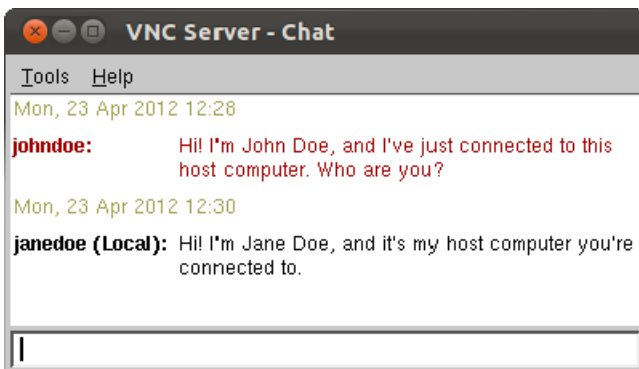

Chatting as a host computer user

A host computer user can participate in a conversation, or start a new one. To start a new conversation as a host computer user:

1. Open the *VNC Server* shortcut menu. *More on this menu.*
2. Select **Chat**. The **VNC Server - Chat** dialog opens. Type text in the field at the bottom:

3. Press the ENTER key to send the message:

Note: A host computer user is identified by the text *(Local)* appended to the user name.

Working with chat

The message box is minimized when chat is not being used. To see it again, hover the mouse over the hot area at the bottom of the *VNC Viewer* window:

Note that the **VNC Server - Chat** dialog can also be minimized. If so, you are notified when new messages appear by the taskbar button flashing (Windows and UNIX/Linux) or a number overlaid on the dock icon (Mac OS X).

Chat messages are stored on the host computer for 90 days. To stop recording messages, select **Tools > Options** in the **VNC Server - Chat** dialog, and turn off **Log chat history**. Alternatively, you can reduce the number of days, or switch to storing a particular number of messages.

To clear the conversation window, delete the `vncchat.xml` file. Under UNIX/Linux and Mac OS X, this file is located in the host computer user's `.vnc` directory (you can configure the location under Windows). Under UNIX/Linux and Mac OS X, you must first stop *VNC Server*, delete the file, and then restart.

Note that when a *VNC Viewer* user disconnects, messages sent by that user change color in the **VNC Server - Chat** dialog.

Disabling and enabling chat

You can disable chat while the current connection is in progress.

To do this, open the **VNC Viewer - Options** dialog and, on the **Inputs** tab, turn off **Enable chat**. *More on this dialog.* The **Start Chat Session**  *VNC Viewer* toolbar button is disabled.

Note: Chat is only disabled for you, and not for any other connected *VNC Viewer* user. You can still view messages in the **VNC Server - Chat** dialog.

You can enable chat again at any time.

Troubleshooting chat

If you cannot use chat, check the following:

1. Are you connected to *VNC Server (Enterprise)* or *VNC Server (Personal)*? You cannot chat to *VNC Server (Free)* users. For more information, see *Connecting to VNC* on page 13.
2. If you are using a previous version of *VNC Viewer* or *VNC Server*, is it at least version 4.5? Chat is not supported by earlier versions.
3. Is there anyone to chat with? The **VNC Server** dialog reveals if any *VNC Viewer* users are connected. *More on this dialog.*

4. Has *VNC Viewer* been configured to disable chat? To see how to enable it again, read *Disabling and enabling chat* on page 69.
5. Has *VNC Server* been configured to prevent chat? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. For more information, see *Preventing chat* on page 94.
6. Has *VNC Server* been configured to prevent *you* chatting? If this is the case and you do not have access to the host computer, you will need to consult your system administrator or a host computer user. If you *do* have access to the host computer, and sufficient privileges to configure *VNC Server*, you may be able to allow it again. Alternatively, you may be able to connect as a different host computer user and use this feature. For more information, see *Restricting features for particular connected users* on page 114.

Setting Up VNC Server

Once licensed, *VNC Server* permits connections to the host computer on which it runs out-of-the-box. You should not need to configure it. However, you can change almost any aspect to suit your requirements and environment if you wish.

This chapter explains how to operate *VNC Server*. It also explains advanced scenarios such as running multiple instances concurrently, configuring ports, and restricting access to features for connected users. For comprehensive information on security, see *Chapter 7, Making Connections Secure* on page 97.

This chapter assumes you have access to the host computer and sufficient privileges to configure both it and *VNC Server*. Note that if you are setting up *VNC Server* on your own computer for remote access, some features require a host computer user to be present when the connection is established, and should therefore be avoided.

Stopping VNC Server	95

Licensing VNC Server

VNC Server must be licensed. If it is not, users cannot connect.

For more information on the different types of license available, to compare the remote control features provided by each, and to obtain a permanent or a trial license key, visit www.realvnc.com/products/vnc/licensing/.

Applying a license key

You can apply a license key to *VNC Server* at any time.

You typically do this when you download and install *VNC Server*. You may subsequently do so in order to renew a support and upgrades contract.

1. Open the *VNC Server* shortcut menu. *More on this menu.*
2. Choose **Licensing**. The **VNC Server - Licensing** dialog opens.
3. Follow the instructions. Note you may additionally be prompted to configure *VNC Server*; see *Harmonizing VNC Server* on page 72 for more information.

Note: If you do not have access to a graphical user interface when you need to apply a license key, use the `vnclicense` command line tool instead. For more information, run the command `vnclicense -help` from the directory in which *VNC* programs are installed.

Harmonizing VNC Server

When you apply a license key you may additionally be prompted to configure *VNC Server*. This is typically because your license key entitles you to fewer RealVNC remote control features than *VNC Server* is currently configured to use. You must harmonize *VNC Server* with the license key.

For example, if at the end of a trial you choose to downgrade to *VNC Server (Free)*, you must turn off encryption and system authentication. If you do not, users cannot connect.

Note that it is possible to run more than one instance of *VNC Server* on a computer (see *Running multiple instances of VNC Server* on page 78). If this is the case, you must harmonize all running instances separately. For example, if under UNIX/Linux you have five instances of *VNC Server* running, two in User Mode and three in Virtual Mode, and you apply the new license key to the licensing wizard of a particular instance of User Mode, then you must separately configure:

- The other instance of User Mode.
- All three instances of Virtual Mode.

Until you do, users will not be able to connect to these instances. Note that administrative privileges may be required to perform this operation if you are not the user who started *VNC Server*.

Understanding license scope

Under Windows, a *VNC Server* license key is system-wide. This means it applies to all users with accounts on the computer. Since only two instances of *VNC Server* can run concurrently on a Windows computer (one in Service Mode, and one in User Mode for the currently logged on user), this means that *VNC Server* is always licensed for all users.

Under UNIX/Linux and Mac OS X, however, there is another dimension to license scope. The license to use *VNC Server* not only applies to all computer users, but additionally limits the number of instances of *VNC Server* that can start. For example, if your license entitles you to five 'desktops', attempting to start *VNC Server* for a sixth time fails. For more information, visit www.realvnc.com/products/vnc/documentation/latest/licensing-faq/.

Note: You can quickly see how many instances of *VNC Server* your license permits you to start, and how many of these are currently running. See page 80 for more information.

Note you can start a maximum of five instances of *VNC Server (Free)* on UNIX/Linux and Mac OS X computers. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if flexibility is important to you.

Starting VNC Server

To start *VNC Server*, follow the appropriate instructions for the host computer's platform below.

Note: As soon as *VNC Server* is licensed and started, users can connect. To delay or prevent connections, see *Preventing connections to VNC Server* on page 92.

Windows

VNC Server can start in Service Mode, in User Mode, or both. For more information on these modes, which you might want to use, and why you might want to run more than one instance of *VNC Server*, see *Running multiple instances of VNC Server* on page 78.

To start *VNC Server*:

- In Service Mode, select **RealVNC > VNC Server** from the **Start** menu. Note administrative privileges are required to perform this operation.

Note: By default, *VNC Server* automatically starts as a service when the computer is powered on. If you explicitly stop *VNC Server*, however, the service does not automatically restart when the computer is rebooted.

- In User Mode, select **RealVNC > Advanced > VNC Server (User Mode)** from the **Start** menu.

Note: Microsoft User Account Control severely restricts users connected to *VNC Server* in User Mode from fully controlling a host computer running Windows Vista or later.

The **VNC Server** dialog opens:

(In this picture, VNC Server is running in Service Mode.)

The **VNC Server** dialog is the gateway to VNC Server and all its features. *More on this dialog.*

Click the **Hide** button to minimize the **VNC Server** dialog but keep VNC Server running in the background.

To access the dialog again, double-click the VNC Server icon  in the Notification area. *More on this icon.*

To see how to explicitly stop VNC Server, or to learn why VNC Server might stop automatically, read *Stopping VNC Server* on page 95.

UNIX/Linux

VNC Server can start in User Mode, in Virtual Mode, or both, as many times as your license permits. For more information on these modes, which you might want to use, and why you might want to run more than one instance of VNC Server, see *Running multiple instances of VNC Server* on page 78.

Note: VNC Server can also start in Service Mode, as soon as the host computer boots, and irrespective of whether or not a host computer user is logged on. For more information on this mode in this release, visit www.realvnc.com/products/vnc/documentation/latest/misc/reference/vncserver-x11-serviced.

To start VNC Server:

- In User Mode, either:
 - Select **Applications > Internet > VNC Server (User Mode)** from the menu system, if available.
 - Run the command `vncserver-x11` in a Terminal window, and press the ENTER key. Note you should *not* do this as a user with administrative privileges.

The **VNC Server** dialog opens:

The **VNC Server** dialog is the gateway to VNC Server in User Mode and all its features. *More on this dialog.*

Under most versions of UNIX and Linux, you can click the **Hide** button to minimize the **VNC Server** dialog but keep VNC Server in User Mode running in the background. To access the dialog again, click the VNC Server icon  in the Notification Area. *More on this icon.*

- In Virtual Mode, run the command `vncserver-virtual` in a Terminal window, and press the ENTER key. Note you should *not* do this as a user with administrative privileges. A message ending with text similar to the following appears:

```
New desktop is johndoe:1 (192.168.0.187:1)
```

This operation starts VNC Server in Virtual Mode attached to a *virtual* desktop, detached from the monitor, and independent of the console. This means that no VNC Server icon and **VNC Server** dialog comparable to those found in User Mode can be displayed. To see how to work with VNC Server in this mode, read *Working with VNC Server in Virtual Mode* on page 77.

A virtual desktop is assigned an X Server session number corresponding to the port on which VNC Server is listening for connection requests. In the example above, this is session number 1, corresponding to port 5901. For more information on ports, see *Configuring ports* on page 88.

To see how to explicitly stop VNC Server, or to learn why VNC Server might stop automatically, read *Stopping VNC Server* on page 95.

Mac OS X

VNC Server can start in Service Mode, in User Mode, or both. In addition, VNC Server can start in User Mode (for different users) as many times as your license permits. For more information on these modes, which you might want to use, and why you might want to run more than one instance of VNC Server, see *Running multiple instances of VNC Server* on page 78.

To start VNC Server:

- In Service Mode, navigate to the **Applications > RealVNC** folder, and double-click the **VNC Server** program. Note administrative privileges are required to perform this operation.
Note: VNC Server automatically starts when the computer powers on.
- In User Mode, navigate to the **Applications > RealVNC > Advanced** folder, and double-click the **VNC Server (User Mode)** program.

The **VNC Server** dialog opens:

(In this picture, VNC Server is running in Service Mode.)

The **VNC Server** dialog is the gateway to VNC Server and all its operations. *More on this dialog.*

Click the **Hide** button to minimize the **VNC Server** dialog but keep VNC Server running in the background.

To access the dialog again, click the VNC Server icon  in the Status bar and, from the shortcut menu, select **Open**. *More on this icon.*

To see how to explicitly stop VNC Server, or to learn why VNC Server might stop automatically, read *Stopping VNC Server* on page 95.

Working with VNC Server in Virtual Mode

Note: The information in this section applies to *VNC Server* for UNIX/Linux only.

VNC Server in Virtual Mode starts unattached to any physical display hardware. This means that desktop artifacts to help you work with *VNC Server*, such as a *VNC Server* icon and **VNC Server** dialog, are not available.

To configure *VNC Server* in Virtual Mode, you can instead:

- Specify parameters on start-up. See *Specifying parameters on start-up* on page 77.
- Configure *VNC Server* as a connected user. See *Configuring VNC Server as a connected user* on page 77.

Note that changes made using either method are lost when *VNC Server* stops.

Specifying parameters on start-up

You can configure *VNC Server* in Virtual Mode on start-up using parameters.

Parameters can be specified in configuration files, in which case they apply to all instances of *VNC Server* in Virtual Mode automatically, or at the command line when a particular instance starts. *VNC Server* reads parameters in the following order:

1. The system configuration file: `/etc/vnc/config.d/Xvnc`.
2. The configuration file of the user starting *VNC Server*: `$HOME/.vnc/config.d/Xvnc`.
3. Appended to the `vncserver-virtual` command at the command line.

Parameters specified later in this list override duplicates specified earlier.

For a full list of parameters, run the command `vncserver-virtual -list`. For more information, run the command `man vncserver-virtual`.

Configuring VNC Server as a connected user

You can connect to *VNC Server* in Virtual Mode and configure it as a connected user. When you disconnect, your changes apply to all future connections to this instance of *VNC Server* while it runs.

Note: To see how to use *VNC Viewer* to connect to *VNC Server*, read *Connecting to a host computer* on page 37. You will need to qualify the network address of the host computer with the X Server session number assigned when *VNC Server* starts, for example `192.168.0.187:1`.

Under most versions of UNIX/Linux, when you connect, a *VNC Server* icon  is visible to the connected user. For more information on this icon, including how to use it to open the **VNC Server** dialog and configure *VNC Server*, start with *Using the VNC Server icon* on page 81.

Note: If another user connects, the *VNC Server* icon is shaded black.

Running multiple instances of VNC Server

Under any platform, and providing your license entitles you to do so, you can run more than one instance of *VNC Server* on a host computer.

This powerful feature means you can set up the host computer so users can connect to it in different ways. For example, you could set up one instance of *VNC Server* so that connections to it are optimized for speed, and another so connections are optimized for security. *VNC Server* facilitates this using *modes*, each of which permits a different level of access to the host computer.

Note: To see how to start *VNC Server* in different modes, read *Starting VNC Server* on page 73.

For more information, read the section appropriate to the platform of the host computer below.

Windows

Under Windows, a host computer user with administrative privileges can start *VNC Server* in Service Mode. This means *VNC Server* runs, and users can connect, irrespective of whether or not a host computer user is logged on. By default, in order to connect to:

- *VNC Server (Enterprise)* or *VNC Server (Personal)*, users must know the user name and password of a member of the Administrators group.
- *VNC Server (Free)*, users must know the VNC password.

In addition, or alternatively, a host computer user can log on and start *VNC Server* in User Mode. This means *VNC Server* runs, and users can connect, just while this host computer user is logged on (connections are terminated at log off). By default, in order to connect to:

- *VNC Server (Enterprise)* or *VNC Server (Personal)*, users must know the user name and password of the currently logged on host computer user.
- *VNC Server (Free)*, users must know the VNC password.

Note: Microsoft User Account Control severely restricts users connected to *VNC Server* in User Mode from fully controlling a host computer running Windows Vista or later. The connected user loses mouse and keyboard control if a program requiring administrative privileges is run (this may or may not be preceded by a User Account Control prompt), and can only continue if a host computer user closes the program, or accepts the prompt.

Once connected to *VNC Server* in either Service Mode or User Mode, users have the same privileges (that is, access rights) on the host computer as the *currently logged on host computer user*. For more information, see *Authenticating connections to VNC Server* on page 98.

Because only one host computer user can log on to a Windows computer at a time, this means a maximum of two instances of *VNC Server* can run concurrently on a Windows host computer – one in Service Mode, and one in User Mode for the currently logged on host computer user. Both instances must listen on different ports; see *Configuring ports* on page 88 for more information.

UNIX/Linux

Under UNIX/Linux, a host computer user can log on and start *VNC Server* in User Mode. In this mode, *VNC Server* runs attached to the console X Server session, which means that:

- A *VNC Server* icon and **VNC Server** dialog are displayed in order to help the host computer user configure *VNC Server* after it has started, if necessary.
- Connected users can access applications currently running on the host computer.
- *VNC Server* stops, and all connections are terminated, when the host computer user starting *VNC Server* logs off.
- By default, in order to connect to:
 - *VNC Server (Enterprise)* or *VNC Server (Personal)*, users must know the user name and password of the host computer user starting *VNC Server*.
 - *VNC Server (Free)*, users must know the VNC password.

Once connected, users have the same privileges (that is, access rights) as this host computer user. For more information on privileges, see *Authenticating connections to VNC Server* on page 98.

Depending on the terms of your license, a host computer user can also, or alternatively, log on and start *VNC Server* in Virtual Mode. In this mode, *VNC Server* runs attached to a new *virtual* desktop, detached from the monitor and independent of the console. This means that:

- No *VNC Server* icon or **VNC Server** dialog can be displayed in order to help the host computer user configure *VNC Server* after it has started. To see how to work with *VNC Server* in this mode, read *Working with VNC Server in Virtual Mode* on page 77.
- Connected users cannot access applications currently running on the console of the host computer. Instead, an isolated workspace is provided. Note this powerful feature can help prevent conflicts; each user can be directed to connect to their own instance of *VNC Server* in Virtual Mode, and control a (virtual) desktop independently.
- *VNC Server* does not stop when the host computer user logs off. Users stay connected, and new users can connect. *VNC Server* must be explicitly stopped.
- By default, in order to connect to:
 - *VNC Server (Enterprise)* or *VNC Server (Personal)*, users must know the user name and password of the host computer user starting *VNC Server*.
 - *VNC Server (Free)*, users must know the VNC password.

Once connected, users have the same privileges (that is, access rights) as this host computer user. For more information on privileges, see *Authenticating connections to VNC Server* on page 98.

Under UNIX/Linux, more than one host computer user can log on at a time. Each currently logged on host computer user can start *VNC Server* in either mode, and all instances, for all users, run concurrently. Note that all instances must listen on different ports; see *Configuring ports* on page 88 for more information.

VNC Server can run as many times as your license permits. Each time a host computer user starts *VNC Server* (in either mode), the count of remaining desktops (that is, instances of *VNC Server*) is decremented. To see how many desktops are left, run the command `vnclicense -check`. For example, the output:

```
Licensed desktops: 5
Running desktops: 3
    johndoe: 2
    janedoe: 1
```

means that five *VNC Server* desktops are licensed to run concurrently on this host computer, and three are already running; two started by John Doe, and one by Jane Doe. Two are left to run.

Note: You can release licenses by killing desktops. To see how to do this, read *Stopping VNC Server* on page 95.

Mac OS X

Under Mac OS X, a user with administrative privileges can start *VNC Server* in Service Mode. This means *VNC Server* runs, and users can connect, irrespective of whether or not a host computer user is logged on. By default, in order to connect to:

- *VNC Server (Enterprise)* or *VNC Server (Personal)*, users must know the user name and password of a member of the admin group.
- *VNC Server (Free)*, users must know the VNC password.

Once connected, users have the same privileges (that is, access rights) as the *currently logged on host computer user*. For more information on privileges, see *Authenticating connections to VNC Server* on page 98.

Depending on the terms of your license, a host computer user can also, or alternatively, log on and start *VNC Server* in User Mode. This means *VNC Server* runs, and users can connect, just while this host computer user is logged on (connections are terminated at log off). By default, in order to connect to:

- *VNC Server (Enterprise)* or *VNC Server (Personal)*, users must know the user name and password of the host computer user starting *VNC Server*.
- *VNC Server (Free)*, users must know the VNC password.

Once connected, users have the same privileges (that is, access rights) as this host computer user. For more information on privileges, see *Authenticating connections to VNC Server* on page 98.

Under Mac OS X, providing Fast User Switching is turned on, more than one host computer user can log on at a time. Each currently logged on host computer user can start *VNC Server* in User Mode, and all instances, for all users, run concurrently. Note that all instances, in either mode, must listen on different ports; see *Configuring ports* on page 88 for more information.

VNC Server can run as many times as your license permits. Each time *VNC Server* is started, the count of remaining desktops (that is, instances of *VNC Server*) is decremented. To see how many desktops are left, run the command `/Library/VNC/vnclicense -check` in a Terminal window. For more information on the message that is displayed, see the UNIX and Linux section above.

Working with VNC Server

This section explains basic *VNC Server* features and operations.

Note: For *VNC Server* in Virtual Mode (UNIX/Linux only), the desktop artifacts explained in this section (icons, menus, and dialog boxes) are available only to a *connected* user. For more information, see *Working with VNC Server in Virtual Mode* on page 77.

Using the VNC Server icon

While *VNC Server* is running, a *VNC Server* icon  is displayed:

- Under Windows, in the Notification area. Note under Windows 7, this is hidden by default and accessible only from  to the right of the Taskbar:

Note under Windows XP, the icon may be hidden by other icons.

- Under UNIX/Linux, in the Notification Area:

Note: Some versions of UNIX are not able to display a *VNC Server* icon.

- Under Mac OS X, on the Status Bar:

The *VNC Server* icon:

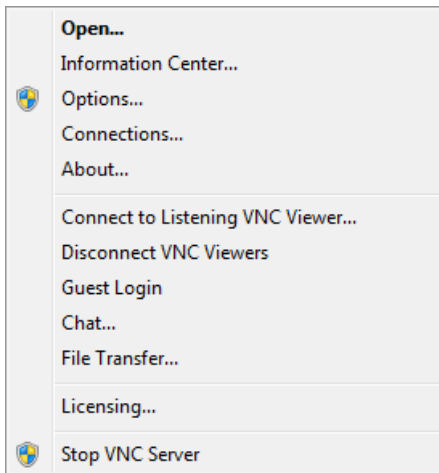

- Provides visual confirmation that *VNC Server* is running on the host computer. If the icon is not available, then typically *VNC Server* is not running.
- Provides visual confirmation that *VNC Server* is configured correctly on the host computer. If not, a red error glyph  appears. Open the **VNC Server** dialog to begin diagnosing the problem. *More on this dialog.*
- Confirms whether users are connected or not. When the first user connects, the icon is shaded black . When the last user disconnects, the icon reverts color again.
- Provides convenient notification of the mode. Hover the mouse cursor over the icon:

- Has a shortcut menu that performs useful operations. *More on this menu.*

Using the VNC Server shortcut menu

VNC Server has a shortcut menu to facilitate common operations. To show it, right-click (click under Mac OS X) the VNC Server icon. *More on this icon.*

(Note menu options are disabled if they are not applicable.)

Note: The shortcut menu is also available from the **More** button on the **VNC Server** dialog. *More on this dialog.*

The following table explains the purpose of each shortcut menu option.

Option	Purpose
Open	Operate VNC Server. See <i>Using the VNC Server dialog</i> on page 83.
Information Center	Understand and resolve issues affecting VNC Server, and retrieve system diagnostics. See <i>Using the VNC Server - Information Center dialog</i> on page 87.
Options	Configure VNC Server. Note administrative privileges are required to perform this operation. See <i>Using the VNC Server - Options dialog</i> on page 88.
Connections	Identify connected users. See <i>Identifying connected users</i> on page 86.
About	See version and trademark information, and access a list of open source dependencies.
Connect to Listening VNC Viewer	Establish a reverse connection in conjunction with a client computer user. See <i>Establishing a reverse connection</i> on page 107.
Disconnect VNC Viewers	Disconnect all users. Note that, by default, users can immediately reconnect.
Guest Login	When turned on, and providing VNC Server is configured correctly, a Guest is allowed to connect, bypassing VNC Server's authentication mechanism. See <i>Allowing a Guest to connect</i> on page 108. Not available in VNC Server (Free).

Option	Purpose
Chat	Chat with all connected users. See <i>Communicating securely using chat</i> on page 67. Not available in <i>VNC Server (Free)</i> .
File Transfer	Send files to all connected users. See <i>Transferring files between client and host computers</i> on page 62. Not available in <i>VNC Server (Free)</i> .
Licensing	Apply a license key to <i>VNC Server</i> . See <i>Licensing VNC Server</i> on page 72.
Stop VNC Server	Stop <i>VNC Server</i> , disconnecting all users. Note administrative privileges are required to perform this operation. See also <i>Stopping VNC Server</i> on page 95.

Using the VNC Server dialog

The **VNC Server** dialog is the gateway to *VNC Server*, and the first port of call for connection information and troubleshooting:

To open the **VNC Server** dialog, click its taskbar entry in the normal way for a program, or alternatively select **Open** from the *VNC Server* shortcut menu. *More on this menu.*

The **VNC Server** dialog:

- Confirms the license type and mode. See *Confirming key information* on page 84.
- Reveals whether *VNC Server* is ready to accept connections. See *Troubleshooting VNC Server* on page 84.
- Provides information to help users connect. Start with *Getting users connected* on page 84.
- Displays the *VNC Server* signature. See *Uniquely identifying VNC Server* on page 86.

- Identifies any connected users. See *Identifying connected users* on page 86.
- Shows expiry dates for trials or support and upgrades contracts. See *Showing expiry dates* on page 87.

Note: The **VNC Server** dialog also has a **More** button providing access to the same features as the **VNC Server** shortcut menu. *More on this menu.*

Confirming key information

The status bar confirms the license type and mode:

You can apply a license key at any time. See *Licensing VNC Server* on page 72 for more information.

For more information on modes, start with *Running multiple instances of VNC Server* on page 78.

Troubleshooting VNC Server

The colored status bar is green if **VNC Server** is configured correctly:

Note there may be messages to read:

A message indicates that, while **VNC Server** is configured correctly, some minor aspect could be improved.

The status bar turns amber if there are warnings:

A warning does not prevent users connecting, but indicates that some important aspect of **VNC Server**, such as performance or security, could be improved.

The status bar turns red if there are errors:

An error must be fixed before users can connect.

To read messages, and resolve warnings and errors, click the **Show** button to open the **VNC Server - Information Center** dialog, and follow the instructions. *More on this dialog.*

Getting users connected

The **Get Started** section identifies **VNC Server** running on the host computer over a private network. (For equivalent information for Internet connections, see *Connecting over the Internet* on page 28.) You can right-click to copy and paste information into an email or similar to help prospective users quickly get connected.

For example:

In this picture, *VNC Server* is running on a host computer with a private network address of 192.168.0.133. In addition:

- *VNC Server* is listening for connections on port 5980. The port number is separated from the network address by a single colon, which means it represents a port in the range 5901 to 5999. Note that:
 - If the port number is separated from the network address by two colons, it represents a port outside the range 5900 to 5999, so for example 192.168.0.133::80 means *VNC Server* is listening on port 80.
 - If no port number is displayed, *VNC Server* is listening on the default port for VNC, 5900.
- *VNC Server (Enterprise)* or *VNC Server (Personal)* is serving *VNC Viewer for Java* on port 5880.

For more information on ports, start with *Configuring ports* on page 88.

Listing all connectivity options

The **Connectivity** section lists all network addresses and other means of identifying *VNC Server* over a private network (for equivalent information for Internet connections, see *Connecting over the Internet* on page 28):

In this picture:

- Two IPv4 network addresses are displayed.
- Four IPv6 network addresses are displayed. Note these are only valid in an IPv6-enabled environment.
- The Bonjour or Avahi name is displayed. Note only Zeroconf-enabled applications such as *VNC Viewer for Android* or *VNC Viewer for iOS* are able to discover *VNC Server*. (*VNC Viewer* is not Zeroconf-enabled in this release.)

Uniquely identifying VNC Server

For *VNC Server (Enterprise)* and *VNC Server (Personal)*, the **Get Started** section displays a signature uniquely identifying *VNC Server*:

When a user connects to *VNC Server* for the first time, that person is asked to verify this signature. For more information on this security feature, see *Uniquely identifying VNC Server* on page 118.

Identifying connected users

The connection bar confirms the number of currently connected users (this bar is only shown if users are connected):

Click the **Details** button to identify and manage connected users. The **VNC Server - Connections** dialog opens:

In this example, the user of client computer 192.168.0.168:

- Authenticated to *VNC Server* using the credentials of johndoe. For more information on authentication, start with *Authenticating connections to VNC Server* on page 98.
- Has a Full set of VNC permissions, permitting unrestricted access to supported RealVNC remote control features while the connection is in progress. For more information, see *Restricting features for particular connected users* on page 114.

Click the **Disconnect** button to disconnect a selected user.

Showing expiry dates

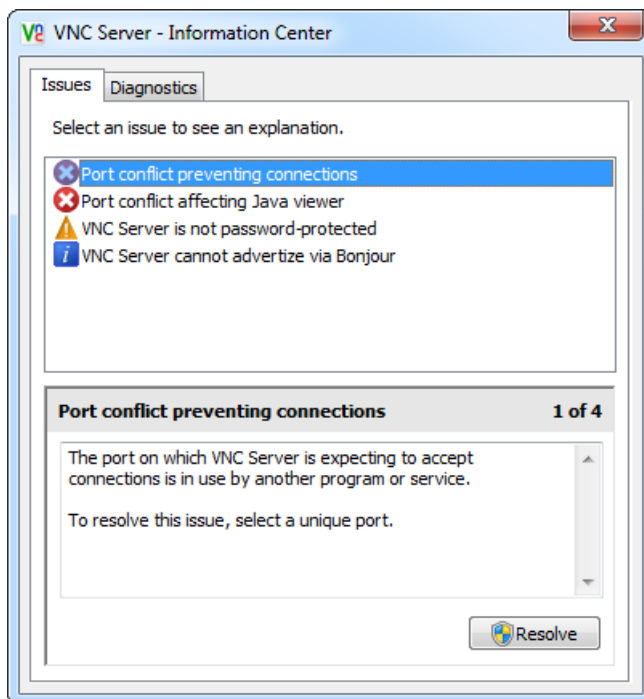

The **Details** section reveals expiry dates for *VNC Server (Enterprise)* or *VNC Server (Personal)*:

- If you are trialling *VNC Server*, you are informed of the date on which your trial expires.
- If you have purchased *VNC Server*, you are informed of the date on which your support and upgrades contract expires.

Using the VNC Server - Information Center dialog

The **VNC Server - Information Center** dialog enables you to:

- Repair *VNC Server*. On the **Issues** tab, follow the instructions for each issue.
- Get system diagnostics in preparation for sending to Technical Support. On the **Diagnostics** tab, click the **Save As** button.
- Find out the address of a router protecting the host computer in preparation for Internet connections. On the **Diagnostics** tab, click the **Test Internet Connection** button. See *Connecting over the Internet* on page 28 for more information.

To open the **VNC Server - Information Center** dialog, either:

- Select **Information Center** from the *VNC Server* shortcut menu. *More on this menu.*
- Click the **Show** button when it appears on the **VNC Server** dialog status bar. *More on this dialog.*

Using the VNC Server - Options dialog

The **VNC Server - Options** dialog enables you to configure VNC Server:

(In this picture, the dialog is in Advanced mode.)

To open the **VNC Server - Options** dialog, select **Options** from the *VNC Server* shortcut menu. *More on this menu.* Note under Windows and Mac OS X, administrative privileges are required to perform this operation.

The first time you open this dialog, it opens in Basic mode, and only one tab is available, containing the most common options. Click the **Advanced** button in the bottom left corner to switch to Advanced mode and see all the tabs in the example above. Note that the **Expert** tab is recommended for expert users only.

For information on most of the options in this dialog, see the subsequent sections in this chapter, starting with *Configuring ports* on page 88. For more information on the options in the **Security** area of the **Connections** tab, and security in general, see *Chapter 7, Making Connections Secure* on page 97.

Note that configuring an option affects all future connections. Unless otherwise stated in the sections that follow, configuring an option affects currently connected users as well.

Configuring ports

By default, *VNC Server* listens for connections on a particular port. In addition, *VNC Server (Enterprise)* and *VNC Server (Personal)* listen for *VNC Viewer for Java* download requests on a different port. You can change these ports, or make them the same.

Note: *VNC Server (Free)* does not listen for *VNC Viewer for Java* download requests. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if this feature is important to you.

By default, two separate ports are assigned when *VNC Server* starts, one for connections and one for download requests:

- Under Windows and Mac OS X, *VNC Server* in both Service Mode and User Mode is assigned port 5900 for connections and port 5800 for download requests.
- Under UNIX/Linux, *VNC Server* in:
 - User Mode is assigned port 5900 for connections and port 5800 for download requests.
 - The first instance of *VNC Server* in Virtual Mode is assigned port 5901 for connections and port 5801 for download requests. Subsequent instances of *VNC Server* in Virtual Mode are assigned port numbers incremented by one, where possible, for example 5902, 5903 (and 5802, 5803), and so on, up to the maximum number of desktops permitted by the host computer's license.

Note: For more information about running multiple instances of *VNC Server*, and the different modes, see *Running multiple instances of VNC Server* on page 78.

If more than one instance of *VNC Server* is running on a host computer, they must all listen on different ports; see below for information on resolving port conflicts. Note, however, that a particular instance of *VNC Server* can listen on the *same* port for connections and download requests; see *Making the connection and download port the same* on page 90 for more information.

Note: When connecting to *VNC Server*, a user must qualify the host computer's network address with the port number in all cases *except* when *VNC Server* is listening for connections on port 5900 only. For more information, see *Qualifying a network address with a port number* on page 30.

Resolving port conflicts

VNC Server must listen for connections and for *VNC Viewer for Java* download requests on a unique port. This is one on which no other instance of *VNC Server*, nor any other program or service, is listening.

Port conflicts disable *VNC Server*. You should be able to resolve them by changing ports on the **Connections** tab of the **VNC Server - Options** dialog. *More on this dialog.*

Changing the connection port

You can change the port on which *VNC Server* is listening for connections. If you do this:

- Users need to know the new port number (if it is not 5900) in order to connect. For more information, see *Qualifying a network address with a port number* on page 30.
- If the host computer is protected by a firewall, then the firewall must be configured to allow incoming network communications to the new port. For more information, see *Allowing network communications through a firewall* on page 31.
- If the host computer is protected by a router and users are connecting over the Internet, then the router must be configured to forward communications to the new port. For more information, see *Configuring a router to forward network communications* on page 29.

To change the port, enter a different number in the **Accept connections on port** field. Note that changing this option does not affect currently connected users.

Changing the download port

You can change the port on which *VNC Server* is listening for *VNC Viewer for Java* download requests. If you do this:

- Web browser users need to know the new port number in order to download. For more information, see *Qualifying a network address with a port number* on page 30.
- If the host computer is protected by a firewall, then the firewall must be configured to allow incoming network communications to the new port. For more information, see *Allowing network communications through a firewall* on page 31.
- If the host computer is protected by a router and web browser users will connect over the Internet, then the router must be configured to forward communications to the new port. For more information, see *Configuring a router to forward network communications* on page 29.

To change the port, enter a different number in the **Serve Java viewer on port** field. Note that changing these options does not affect currently connected users.

Making the connection and download port the same

VNC Server can listen on the same port for connections and download requests. This may simplify firewall configuration and make the host computer more secure.

To use the same port, enter the same number in the **Accept connections on port** and **Serve Java viewer on port** fields. Note that configuring these options does not affect currently connected users.

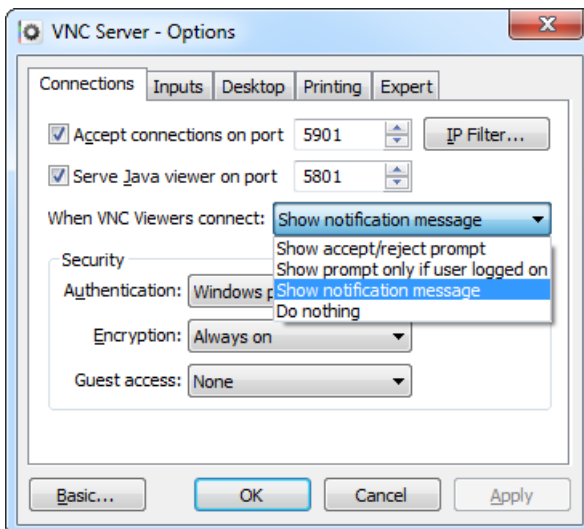

Notifying when users connect

By default, *VNC Server* displays a notification message in the bottom right corner of the host computer's desktop (top right under Mac OS X) each time a user connects:

Note: A similar message appears on disconnection.

You can choose different notification options on the **Connections** tab of the **VNC Server - Options** dialog. *More on this dialog.*

Preventing notification messages

You can disable notification messages on connection and disconnection. To do this, choose *Do nothing*.

Displaying connection prompts

You can replace messages with connection prompts that enable a host computer user (or an already-connected user) to accept or reject new users. To do this, choose *Show accept/reject prompt*.

Note: Some users (those with sufficient VNC permissions) are able to bypass connection prompts.

Alternatively, you can *conditionally* replace messages with connection prompts so that they only appear when a host computer user is 'present' to accept or reject them. To do this, choose *Show prompt only if user logged on* (Service Mode) or *Show prompt only if user connected* (Virtual Mode). For more information, see *Preventing particular users connecting* on page 113.

Preventing connections to VNC Server

By default, as soon as *VNC Server* starts:

- Users can connect to *VNC Server* and begin controlling the host computer.
- Web browser users can download *VNC Viewer for Java* from *VNC Server (Enterprise)* or *VNC Server (Personal)*, and use it to connect.

You can prevent all connection activity by configuring options on the **Connections** tab of the **VNC Server - Options** dialog. *More on this dialog.*

Note: You can alternatively prevent *particular* users connecting, or connections from *particular* client computers. See *Preventing particular connections to VNC Server* on page 111 for more information.

Preventing all connections

You can prevent all users connecting to *VNC Server*. To do this, turn off **Accept connections on port**. Note that configuring this option does not affect currently connected users.

Note: If the dialog is in Basic mode, this option is called **Allow VNC Viewers to connect to VNC Server**.

You can still use *VNC Server* to establish a reverse connection to a client computer. For more information, see *Establishing a reverse connection* on page 107.

Preventing all VNC Viewer for Java downloads

You can prevent all web browser users downloading *VNC Viewer for Java*. To do this, turn off **Serve Java viewer on port**. Note that configuring this option does not affect currently connected users.

Restricting functionality for connected users

By default, any number of users can connect to an instance of *VNC Server* running on a host computer. Each user can:

- Control the host computer using their client computer's keyboard and mouse, for example running applications, changing settings, and accessing data (according to their privileges on the host computer).
- Copy and paste text between applications running on the client and host computers.

In addition, for connections to *VNC Server (Enterprise)* and *VNC Server (Personal)*, users can:

- Print host computer files to a printer attached to the client computer.
- Exchange files with the host computer.
- Chat with other *VNC Viewer* users connected to the same host computer, or with a host computer user.

You can restrict access to RealVNC remote control features for all connected users, if necessary, by configuring options on the **Inputs** tab of the **VNC Server - Options** dialog. *More on this dialog.*

Note: In some circumstances, you can restrict access to features for *particular* users by revoking VNC permissions. See *Restricting features for particular connected users* on page 114 for more information.

Making VNC Server ‘view only’

You can quickly prevent all interchange with all client computers, making the host computer ‘view only’. This might be useful in an educational environment, for example, when multiple users are connected but must not interact. To do this, select *Disabled (view-only mode)* from the **Inputs** dropdown.

Disabling the keyboards of client computers

You can disable the keyboards of all client computers. To do this, turn off **Enable keyboard input**.

Disabling the mice of client computers

You can disable the mice of all client computers. To do this, turn off **Enable mouse input**.

Preventing printing

For *VNC Server (Enterprise)* and *VNC Server (Personal)*, you can prevent all connected users printing host computer files to local printers. To do this, turn off **Allow VNC Viewers to share printers**. Note this option is on the **Printing** tab. For more information about this feature, see *Printing host computer files to a local printer* on page 60.

Under UNIX/Linux, if you have root privileges on the host computer, you can disable printing system-wide. To do this, run the command `vncinitconfig -disable-print` in a Terminal window, and press the ENTER key. The **Printing** tab is disabled. To reverse this, run the command `vncinitconfig -enable-print`.

Under Windows, if you have sufficient privileges on the host computer, you can disable printing system-wide by re-installing *VNC Server* without the VNC Printer Driver component. To do this, turn off **VNC Printer Driver** at the appropriate step in the Installation Wizard. For more information on installation, visit www.realvnc.com/products/vnc/documentation/latest/installing-removing/windows. The **Printing** tab is disabled.

Preventing file transfer

For *VNC Server (Enterprise)* and *VNC Server (Personal)*, you can prevent all connected users exchanging files with the host computer. To do this, turn off **Share files with VNC Viewers**. For more information about this feature, see *Transferring files between client and host computers* on page 62.

Preventing copy and paste text

You can prevent all connected users copying and pasting text between applications running on the client and host computers. To do this, turn off **Share clipboard with VNC Viewers**. For more information about this feature, see *Copying and pasting text between client and host computers* on page 66

Note: Under Windows, note that *files* can be copied and pasted by connected users to client computers also running Windows. To prevent this, turn off **Share files with VNC Viewers**.

Preventing chat

For *VNC Server (Enterprise)* and *VNC Server (Personal)*, you can prevent connected users communicating securely using chat. To do this, turn off **Enable chat**. For more information about this feature, see *Communicating securely using chat* on page 67.

Stopping VNC Server

VNC Server runs until it is stopped.

To explicitly stop VNC Server:

- In all modes and under all platforms *except* Virtual Mode on UNIX/Linux, select **Stop VNC Server** from the VNC Server shortcut menu. *More on this menu*. Administrative privileges are required to perform this operation.

Note: Under Windows, VNC Server in Service Mode will not automatically restart if you do so and then reboot the host computer.

- To stop VNC Server in Virtual Mode, run the command `vncserver -kill :x`, where `x` is the X Server session number. For more information, see page 75.

Note that VNC Server automatically stops:

- In Service Mode (Windows and Mac OS X) and in Virtual Mode (UNIX/Linux), when the host computer is powered down.
- In User Mode (all platforms), when the host computer starting it logs off or the host computer is powered down.

VNC Server can also stop under the following circumstances:

- Under Windows, VNC Server in User Mode stops automatically when the last user disconnects if the **When last VNC Viewer disconnects** option is changed to `Logoff user`. For more information, see *Protecting the host computer* on page 119.
- A connected user can explicitly stop VNC Server if they know the credentials of an administrative user.
- A connected user can log off and/or power down the host computer.

To see how to start VNC Server again, read *Starting VNC Server* on page 73.

7

Making Connections Secure

VNC Server (Enterprise) and *VNC Server (Personal)* are designed to permit authenticated and encrypted connections between a host and any number of client computers out-of-the-box. This chapter explains how to configure *VNC Server* to relax the authentication and encryption rules if you consider it safe to do so. Conversely, you can tighten the encryption rules for *VNC Server (Enterprise)* if required.

Note: *VNC Server (Free)* can only authenticate connections. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if security is important to you.

This chapter also explains how to configure *VNC Server* to protect the host computer from accidental or malicious damage by *particular* connected users, either by restricting their access to RealVNC remote control features while connections are in progress, or by preventing them from connecting in the first place.

Contents

Restricting features for particular connected users	114
Uniquely identifying VNC Server	118
Protecting privacy	118

Authenticating connections to VNC Server

By default, users must authenticate in order to connect to *VNC Server*. Note this is *not* the same as logging on to the host computer (though the same credentials may be used for both).

By default:

- *VNC Server (Enterprise)* and *VNC Server (Personal)* specify system authentication. This means that a user must supply the credentials of a host computer user in order to connect. See *Authenticating using host computer user credentials* on page 98.
- *VNC Server (Free)* specifies VNC authentication. This means that a user must supply a password specific to VNC in order to connect. See *Authenticating using a VNC password* on page 103.

You can relax the authentication rules, or allow particular users to bypass them altogether, if you consider it safe to do so. For more information, start with *Relaxing the authentication rules* on page 104.

Authenticating using host computer user credentials

By default, *VNC Server (Enterprise)* and *VNC Server (Personal)* specify system authentication, which means that *VNC Server* is integrated into the credentialing system of the host computer. This mechanism is typically both secure and convenient; system administrators commonly force the adoption of complex user names and passwords in enterprise environments, and users with their own accounts on the host computer can authenticate using already-familiar credentials.

Note: *VNC Server (Free)* does not support system authentication. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if security is important to you.

Note that in some circumstances, the primary user account on the host computer might not have a password set (likely for friends and family only). If so, the authentication mechanism must be changed to VNC authentication, or turned off altogether. A user cannot specify a blank password in order to connect.

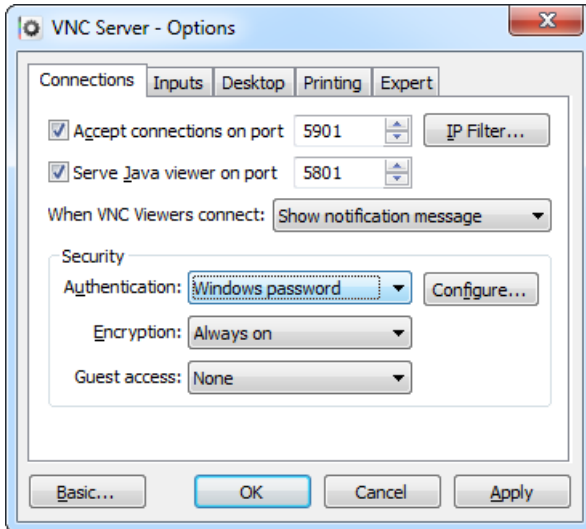

By default, the user name and password of a host computer user *with administrative privileges* must be published to prospective users. Once connected, users:

- Acquire a set of privileges (that is, access rights) on the host computer enabling particular operations to be performed. Note this is not necessarily administrative privileges, even if the credentials of such a user were entered in order to connect.
- Are granted a Full set of VNC permissions, permitting access to all RealVNC remote control features while the connection is in progress.

You can configure *VNC Server* in order to publish the credentials of a non-administrative host computer user if you wish to either obscure administrator credentials, restrict VNC permissions, or both. Consult the section appropriate to the operating system of the host computer below for more information.

Windows

Under Windows, system authentication is selected using the Windows password option in the **Authentication** dropdown of the **VNC Server - Options** dialog. *More on this dialog.*

By default, to connect to *VNC Server*:

- In Service Mode, a user must supply the credentials of a member of the Administrators group.
- In User Mode, a user must supply the credentials of the currently logged on host computer user (that is, the user starting *VNC Server*).

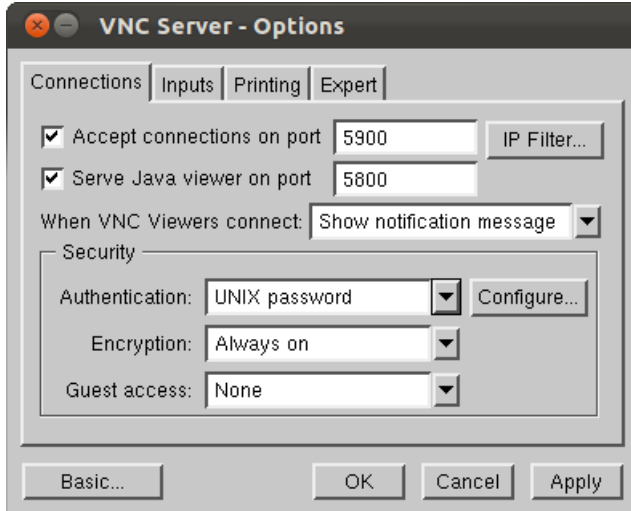

You can add different users or groups to the authentication list if you do not want to publish the credentials of members of the Administrators group. For more information, see *Managing users and groups in the authentication list* on page 102.

Note that the credentials supplied by a user in order to connect to *VNC Server* determine the VNC permissions granted to that user. VNC permissions control which RealVNC remote control features the user is allowed to use. By default, a Full set of VNC permissions is granted. For more information on what this means, and how to revoke VNC permissions in order to restrict access to RealVNC remote control features, see *Restricting features for particular connected users* on page 114.

Once connected, a user has the same privileges (that is, access rights) on the host computer as the *currently logged on host computer user*. This need not be a user with administrative privileges even if the credentials of one were supplied in order to connect to *VNC Server*. The opposite also holds true: a connected user has administrative privileges on the host computer if such a user is currently logged on. Note that if *VNC Server* is running in Service Mode and no host computer user is logged on, the connected user must log on to Windows in order to continue.

UNIX/Linux

Under UNIX/Linux, system authentication is selected using the `UNIX password` option in the **Authentication** dropdown of the **VNC Server - Options** dialog. *More on this dialog.*

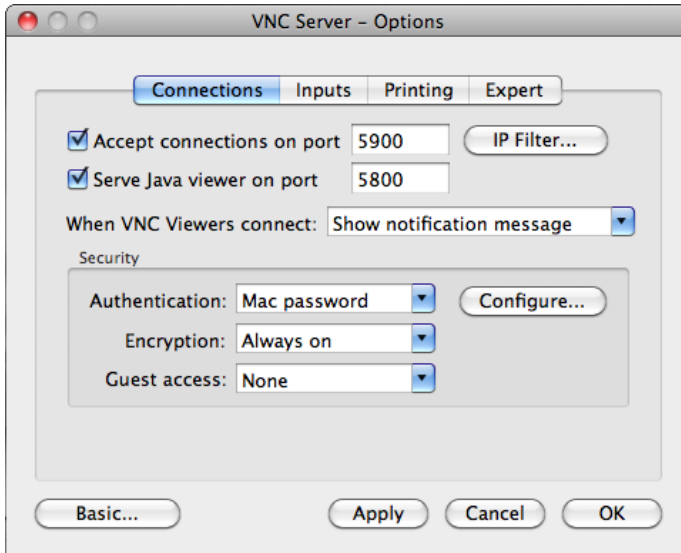

This means, to connect to *VNC Server* in either User Mode or Virtual Mode, a user must supply the credentials of the host computer user starting *VNC Server*. You can add different users or groups to the authentication list if you do not want to publish the credentials of this host computer user. For more information, see *Managing users and groups in the authentication list* on page 102.

Note that the credentials supplied by a user in order to connect to *VNC Server* determine the VNC permissions granted to that user. VNC permissions control which RealVNC remote control features the user is allowed to use. By default, a Full set of VNC permissions is granted. For more information on what this means, and how to revoke VNC permissions in order to restrict access to RealVNC remote control features, see *Restricting features for particular connected users* on page 114.

Once connected, a user has the same privileges (that is, access rights) on the host computer as the host computer user starting *VNC Server*. This need not be a user with administrative privileges even if the credentials of one were supplied in order to connect to *VNC Server*. The opposite also holds true: a connected user has administrative privileges on the host computer if such a user started *VNC Server*.

Mac OS X

Under Mac OS X, system authentication is selected using the `Mac password` option in the **Authentication** dropdown of the **VNC Server - Options** dialog. *More on this dialog.*

This means, to connect to VNC Server:

- In Service Mode, a user must supply the credentials of a member of the admin group.
- In User Mode, a user must supply the credentials of the host computer user starting VNC Server.

You can add different users or groups to the authentication list if you do not want to publish the credentials of host computer users with administrative privileges. For more information, see *Managing users and groups in the authentication list* on page 102.

Note that the credentials supplied by a user in order to connect to VNC Server determine the VNC permissions granted to that user. VNC permissions control which RealVNC remote control features the user is allowed to use. By default, a Full set of VNC permissions is granted. For more information on what this means, and how to revoke VNC permissions in order to restrict access to RealVNC remote control features, see *Restricting features for particular connected users* on page 114.

Once connected to VNC Server:

- In Service Mode, a user has the same privileges (that is, access rights) as the currently logged on host computer user. If no host computer user is logged on, then the user must log on to Mac OS X in order to continue.
- In User Mode, a user has the same privileges as the host computer user starting VNC Server.

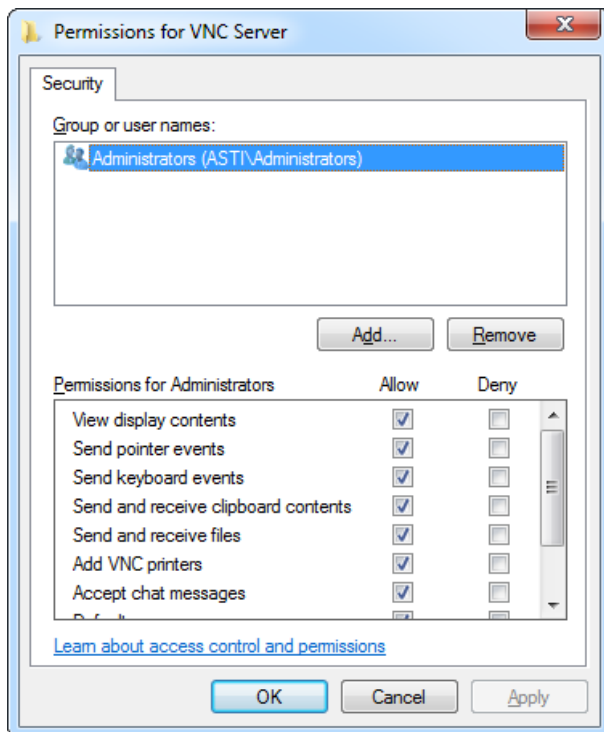

In either case, this need not be a host computer user with administrative privileges even if the credentials of one were supplied in order to connect to VNC Server. The opposite also holds true: a connected user has administrative privileges on the host computer if such a user either started VNC Server (User Mode) or is currently logged on (Service Mode).

Managing users and groups in the authentication list

By default, *VNC Server (Enterprise)* and *VNC Server (Personal)* specify system authentication, which means that a user must supply the credentials of a host computer user in order to connect to *VNC Server*. Under certain circumstances, this may be the credentials of a host computer user with administrative privileges.

If you want to use system authentication but do not want to publish the credentials of host computer users with administrative privileges, you can add host computer users or groups with less sensitive credentials to the *VNC Server* authentication list. (Alternatively, you could just choose a different authentication mechanism; for more information, see *Relaxing the authentication rules* on page 104.)

To manage users and groups in the authentication list, open the **VNC Server - Options** dialog. *More on this dialog.* On the **Connections** tab, click the **Configure** button. Providing Windows password (or platform-specific equivalent) is selected in the **Authentication** dropdown, the **Permissions for VNC Server** dialog opens:

To add a new host computer user or group, click the **Add** button. To remove an existing host computer user or group, select it in the list and click the **Remove** button. Note that a user can supply the credentials of *any* of the host computer users listed in **Group or user names** in order to connect to *VNC Server*.

Note: Artifacts in this dialog have slightly different names under UNIX/Linux and Mac OS X.

Note that when you add a new host computer user or group to the authentication list, a Default set of VNC permissions is granted to connecting users supplying those credentials, even if this host computer user or

group has administrative privileges on the host computer. For more information on VNC permissions, see *Restricting features for particular connected users* on page 114.

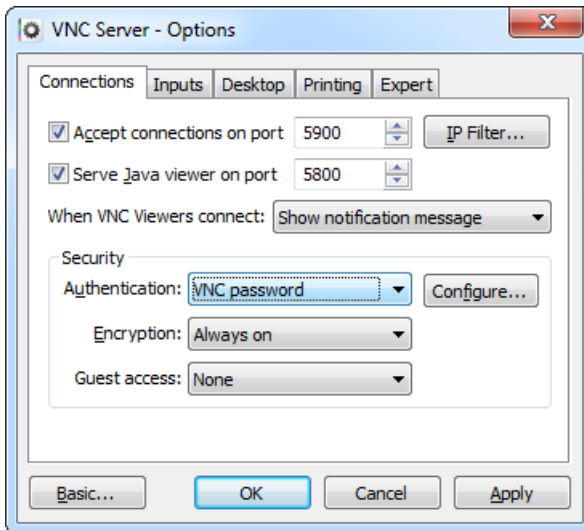

Authenticating using a VNC password

By default, *VNC Server (Free)* specifies VNC authentication, which means that *VNC Server* has its own password, disassociated from the credentialing system of the host computer. Note this mechanism is only as secure as the complexity of the password chosen.

Note: You can specify VNC authentication as the mechanism for *VNC Server (Enterprise)* or *VNC Server (Personal)* if you wish.

To enable connections, a *VNC Server* password must be specified and published to prospective users. Once connected, users acquire a set of privileges (that is, access rights) on the host computer enabling particular operations to be performed. (The same privileges are granted as for system authentication. See *Authenticating using host computer user credentials* on page 98 for more information.)

VNC authentication is selected using the `VNC password` option in the **Authentication** dropdown of the **VNC Server - Options** dialog. *More on this dialog.*

To specify a new password, or change an existing one, click the **Configure** button. The **VNC Server - Password** dialog opens:

Specify and confirm a password, and click the **OK** button. Publish this password to prospective users, and in addition notify that there is no need to enter a user name in the *VNC Viewer Authentication Credentials* dialog, even if its **Username** field is enabled. *More on this dialog.*

Specifying additional passwords

If you choose to use VNC authentication as the mechanism for *VNC Server (Enterprise)* or *VNC Server (Personal)*, you can specify up to two additional passwords, enabling you to differentiate between basic, standard, and power users.

Note: *VNC Server (Free)* does not support additional passwords. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if flexibility is important to you.

Providing the **Extended Configuration** button is enabled, click it to open the **VNC Server - Extended Passwords** dialog:

To give connecting users:

- The power to bypass connection prompts (if enabled), turn on **Enable “Admin” user**, and click the adjacent **Set password** button to specify and confirm an admin password. Publish this password to prospective users, and in addition instruct them to enter a user name of `Admin`. For more information on connection prompts, see *Preventing particular users connecting* on page 113.
- View only access to the host computer, turn on **Enable “ViewOnly” user** and click the adjacent **Set password** button to specify and confirm a view only password. Publish this password to prospective users, and in addition instruct them to enter a user name of `ViewOnly`.

Relaxing the authentication rules

You can relax the authentication rules for all prospective users if you consider it safe to do so. For more information on the default authentication mechanisms, see *Authenticating connections to VNC Server* on page 98.

Note: Alternatively, you can allow *particular* users to bypass authentication altogether. For more information, see *Bypassing the authentication rules* on page 107.

For *VNC Server (Enterprise)*, you can relax the authentication rules so that users:

- Need only enter a VNC password. This forgoes the need to publish host computer user credentials, and for users to have to remember a user name. For more information, see *Authenticating using a VNC password* on page 103.

- Authenticate automatically using the credentials the user has already entered to log on to their *client* computer. This speeds up the connection process and helps prevent password fatigue. For more information, see *Authenticating automatically using client computer user credentials* on page 105.
- Do not have to authenticate at all. This may allow older versions of *VNC Viewer* (or VNC-compatible Viewer technology) that do not support authentication to connect. For more information, see *Turning authentication off* on page 106.

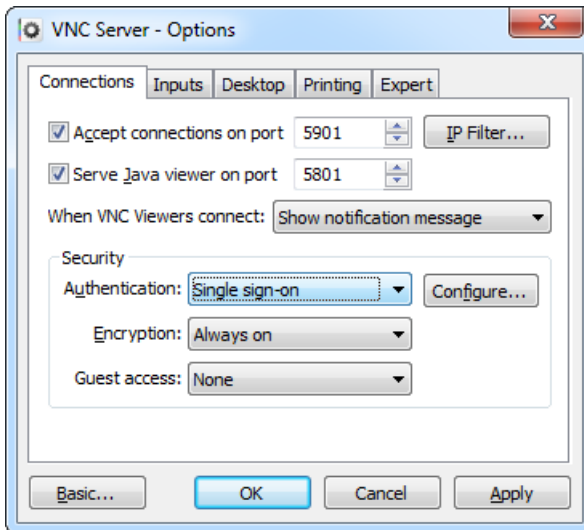

For *VNC Server (Personal)*, you can relax the authentication rules so that users need only enter a VNC password, or do not have to authenticate at all. For *VNC Server (Free)*, you can only relax the rules so that users do not have to authenticate at all. Upgrade the host computer to *VNC Server (Enterprise)* if security is important to you.

Authenticating automatically using client computer user credentials

You can configure *VNC Server (Enterprise)* to authenticate a user automatically using the credentials already entered by that user to log on to their *client* computer. Note this authentication mechanism is only effective in a managed network environment, with (for example) a Kerberos authentication server.

Note: *VNC Server (Free)* and *VNC Server (Personal)* do not support single sign-on. Upgrade the host computer to *VNC Server (Enterprise)* if security is important to you.

To do this, choose the *Single Sign On* option in the **Authentication** dropdown of the **VNC Server - Options** dialog. *More on this dialog.*

There is no need to publish credentials to prospective users. Once connected, users:

- Acquire a set of privileges (that is, access rights) on the host computer enabling particular operations to be performed.
- Are granted a set of VNC permissions, permitting access to RealVNC remote control features for the duration of the connection.

The same privileges and VNC permissions are granted as for system authentication. See *Authenticating using host computer user credentials* on page 98 for more information.

Turning authentication off

You can turn authentication off for all users. Note you should only do this if you are sure all prospective users are trustworthy.

Note: You can allow just *particular* users to connect without supplying a password. See *Bypassing the authentication rules* on page 107 for more information.

To do this, choose the `None` option in the **Authentication** dropdown of the **VNC Server - Options** dialog. *More on this dialog.*

(Note this option is only available when the dialog is in Advanced mode.)

There is no need to publish credentials to prospective users.

Once connected, users acquire a set of privileges (that is, access rights) on the host computer enabling particular operations to be performed. The same privileges are granted as for system authentication. See *Authenticating using host computer user credentials* on page 98 for more information.

Bypassing the authentication rules

You can enable particular users to connect to *VNC Server* without specifying a password, bypassing *VNC Server's* authentication mechanism altogether.

Note: You can turn authentication off for all users if you consider it safe to do so. For more information, see *Turning authentication off* on page 106.

You can either:

- Establish a reverse connection to a particular client computer. See *Establishing a reverse connection* on page 107.
- Allow a particular user to connect as a Guest. See *Allowing a Guest to connect* on page 108. Note this remote control feature is not available in *VNC Server (Free)*.

Clearly, you should only establish reverse connections to client computers with trustworthy potential users, and only allow trustworthy users to connect as Guests. If you are setting up *VNC Server* on your own computer for remote access, note that a user must be present at the host computer for either of these features to work.

Establishing a reverse connection

You may be able to establish a reverse connection to a particular client computer, bypassing the authentication mechanism specified by *VNC Server*.

Note: The client computer must be running *Listening VNC Viewer*. For more information, see *Starting Listening VNC Viewer* on page 34.

Note this feature is also useful if the host computer is protected by a firewall that cannot be configured to allow network communications, or by a router that cannot be configured to forward network communications, thus preventing incoming connections. In a reverse connection, network communications from the host computer are *outgoing*.

To establish a reverse connection:

1. Open the *VNC Server* shortcut menu. *More on this menu.*
2. Select **Connect to Listening VNC Viewer**:

3. If you are connecting:
 - Within a private network, enter the network address of the client computer itself. If you do not know what this is, ask a client computer user to run a command such as `ipconfig` (Windows) or `ifconfig` (Linux and Mac OS X).

- Over the Internet, enter the network address of a router protecting the client computer. If you do not know what this is, you can ask a client computer user to visit www.whatismyip.com.

For more information on private and public networks, start with *Connecting within a private network on page 27*.

Listening VNC Viewer listens for reverse connections on port 5500. If a reverse connection fails, it may be because the client computer is protected by a router and/or a firewall and these have not been configured to allow access to *Listening VNC Viewer* on port 5500. For more information on this, and connection issues in general, see *Troubleshooting connection on page 26*.

When a reverse connection is established, the desktop of the host computer is displayed on the client computer in exactly the same way as it is for *VNC Viewer*. A *Listening VNC Viewer* user can control the host computer exactly as a *VNC Viewer* user does. For more information, see *Chapter 3, Using VNC Viewer on page 33*.

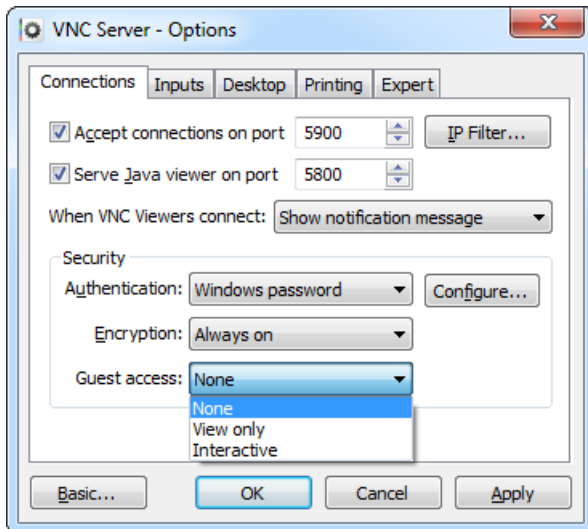

Allowing a Guest to connect

You can allow a particular user to connect to *VNC Server (Enterprise)* or *VNC Server (Personal)* as a Guest, bypassing the authentication mechanism. A Guest typically connects infrequently, or for a short period of time.

Note: *VNC Server (Free)* does not support guest connections. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if flexibility is important to you.

To enable Guests to connect:

1. Open the **VNC Server - Options** dialog. *More on this dialog*. On the **Connections** tab, select an alternative to the default **None** option from the **Guest access** dropdown:

To give users:

- The ability to remote control the host computer, select *Interactive*.

- View only access, select `View-only`. Any keypresses or mouse movements made by the user will have no effect.

2. Turn on the **Guest Login** option on the *VNC Server* shortcut menu. *More on this menu*. A tick appears:

Note: If the **Guest Login** menu option is turned off, Guests cannot connect. Note that other connected users can turn this menu option on and off. When *VNC Server* starts, **Guest Login** is turned off by default.

3. Inform users that they must enter `Guest` in the **Username** field of the **VNC Viewer - Authentication** dialog. *More on this dialog*. The **Password** field, however, should be left empty.

When a Guest connects, a connection prompt appears on the host computer:

A host computer user must accept the connection request within ten seconds or it will be automatically rejected. For more information on connection prompts, see *Preventing particular users connecting* on page 113.

Changing the encryption rules

By default, all network communications to and from a host computer running *VNC Server (Enterprise)* or *VNC Server (Personal)* are encrypted using 128-bit AES technology. Identity is certified using 2048 bit RSA public/private keys.

Note: *VNC Server (Free)* does not support encryption. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if security is important to you.

For *VNC Server (Enterprise)*, you can:

- Relax the encryption rules if you are sure all potential client computers are within a secure network environment, and that eavesdropping is impossible. This may improve performance. It may also allow older versions of *VNC Viewer*, or VNC-compatible Viewer technology, that do not support encryption to connect.

Note: Even if encryption is turned off, passwords are still encrypted.

- Tighten the encryption rules by increasing the AES key size to 256-bit. This makes connections ultra-secure, but may impact performance slightly. It also means only *VNC Viewer 4.6* or later can connect.

For *VNC Server (Personal)*, you can just relax the encryption rules. 256-bit AES encryption is not available. Upgrade the host computer to *VNC Server (Enterprise)* if security is important to you.

Note: A connecting user can request that the encryption rules be tightened, but not relaxed.

To change the rules, open the **VNC Server - Options** dialog. *More on this dialog.* On the **Connections** tab, select an alternative to the default *Always on* option from the **Encryption** dropdown:

Choose:

- *Always maximum* to specify 256-bit AES. Note that only *VNC Viewer 4.6* or later can connect. A connecting user cannot request that encryption be turned off, or the AES key size reduced to 128-bit.
- *Prefer on* to prefer, though not mandate, that connections be encrypted using 128-bit AES. A connecting user can either request that encryption be turned off (by selecting *Prefer off* in the **VNC Viewer** dialog), or the AES key size be increased to 256-bit (by selecting *Always maximum* in the **VNC Viewer** dialog).
- *Prefer off* to prefer, though not mandate, that connections be unencrypted. Choose this option to allow older versions of *VNC Viewer*, or VNC-compatible Viewer technology, to connect. A connecting user can request that encryption be turned back on, either to 128-bit AES (by selecting *Prefer on* or *Always on* in the **VNC Viewer** dialog), or to 256-bit AES (by selecting *Always maximum* in the **VNC Viewer** dialog).

For more information about requesting encryption in the **VNC Viewer** dialog, see *Step 4: Request an encrypted connection on page 22*.

Preventing particular connections to VNC Server

You can prevent particular users connecting to VNC Server. You can either:

- Prevent connections from particular client computers. See *Preventing connections from particular client computers* on page 111.
- Prevent particular users connecting. See *Preventing particular users connecting* on page 113.

Note: You can prevent *all* users connecting to VNC Server. For more information, see *Preventing connections to VNC Server* on page 92.

Preventing connections from particular client computers

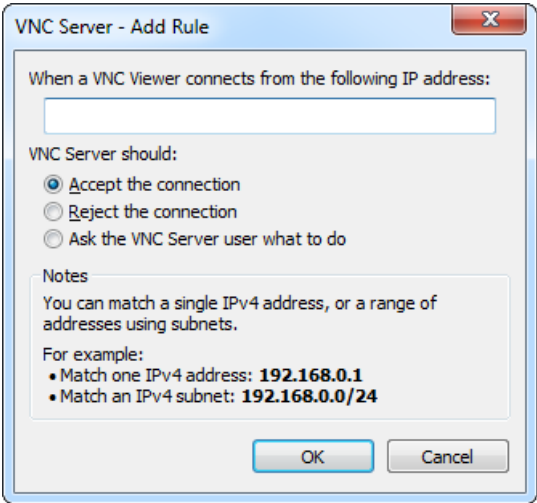

You can prevent all connections originating from particular client computers by filtering the network addresses of those client computers.

Note: If you filter network addresses, users can no longer enter host computer IPv6 network addresses in order to connect to VNC Server (even from an authorized client computer).

To filter network addresses, open the **VNC Server - Options** dialog. *More on this dialog.* On the **Connections** tab, click the **IP Filter** button:

By default, connection requests are accepted from all client computers. To reject connection requests from a particular client computer, click the **Add** button:

Specify the network address, or range of addresses, in IPv4 format, and then choose one of the following options.

Option	Explanation
Accept the connection	Accepts connection requests from the specified client computer(s).
Reject the connection	Rejects connection requests from the specified client computer(s).
Ask the VNC Server user what to do	Displays connection prompts enabling a host computer user to either accept connection requests, allow 'view only' access, or reject requests from the specified client computer(s). If no host computer user is present, connection requests are automatically rejected after 10 seconds. For more information on connection prompts, see <i>Preventing particular users connecting</i> on page 113.

Note that if you do filter network addresses, the order of rules in the **VNC Server - Filter Rules** dialog is important. The first matching rule determines what happens to connection requests from a particular client computer. For example, if a rule rejecting a client computer is encountered before one accepting it, then all connection requests from that client computer will be rejected. You can move rules up and down in the dialog using the arrows.

By default, the `Default` rule *accepts* connection requests from all client computers. You can change this so that it rejects or queries all connection requests instead. To do this, select the `Default` rule, and click the **Edit** button. Note this rule is always last in the dialog.

Preventing particular users connecting

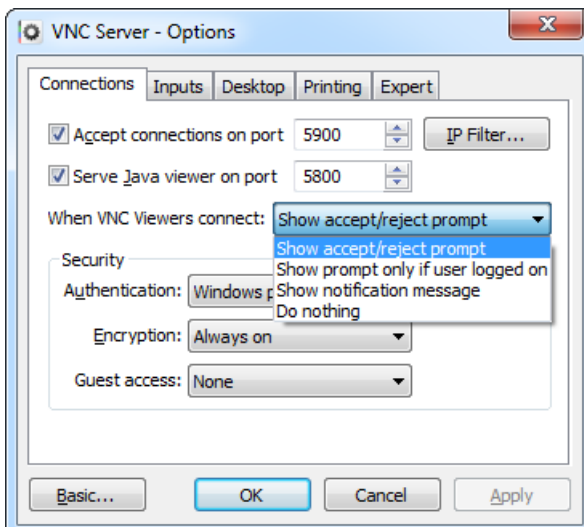

You can prevent a particular user connecting by causing a connection prompt to appear on the host computer's desktop:

A connection prompt enables a host computer user (if one is present), or an already-connected user, to identify the connecting user and either accept the connection request, allow 'view only' access to the host computer, or reject it. If no response is received within ten seconds, then the connection request is automatically rejected. Note that if you are setting up VNC Server on your own computer for remote access then enabling this feature may prevent you connecting.

Note: In some circumstances, certain users connecting to VNC Server (*Enterprise*) or VNC Server (*Personal*) are able to bypass connection prompts. To submit these users to prompts, revoke the `Connect without accept/reject prompt` VNC permission. For more information, see *Customizing VNC permissions* on page 115.

To display connection prompts, open the **VNC Server - Options** dialog. *More on this dialog.* On the **Connections** tab, choose `Show accept/reject prompt` from the **When VNC Viewers connect** dropdown:

In certain circumstances, you may be able to *conditionally* display connection prompts:

- For *VNC Server* in Service Mode (Windows and Mac OS X), choose `Show prompt only if user logged on` in order to automatically accept connections when no host computer user is currently logged on (and therefore unlikely to be present). Note that at least one newly-connected user must then log on to the operating system of the host computer in order to continue. Subsequently, connection prompts are displayed again, for this user to accept or reject.
- For *VNC Server* in Virtual Mode (UNIX/Linux), choose `Show prompt only if user connected` to automatically accept the first connection (since no host computer user can be 'present' at a virtual desktop). Subsequently, connection prompts are displayed again, for this user to accept or reject.

For more information on notifications, see *Notifying when users connect* on page 91.

Restricting features for particular connected users

A set of VNC permissions is granted to each user who connects to *VNC Server (Enterprise)* or *VNC Server (Personal)* using either of the following authentication mechanisms:

- System authentication. See *Authenticating using host computer user credentials* on page 98.
- Single sign-on. See *Authenticating automatically using client computer user credentials* on page 105. Note this authentication mechanism is only available in *VNC Server (Enterprise)*.

Note: *VNC Server (Free)* does not support VNC permissions. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if security and flexibility are important to you.

VNC permissions control which RealVNC remote control features a connected user is allowed to use. By default, a user supplying the credentials:

- Of a host computer user with administrative privileges is granted a Full set of VNC permissions.
- Of any other host computer user is granted a Default set of VNC permissions.

The following table explains VNC permissions (and the groups in which they may be allocated):

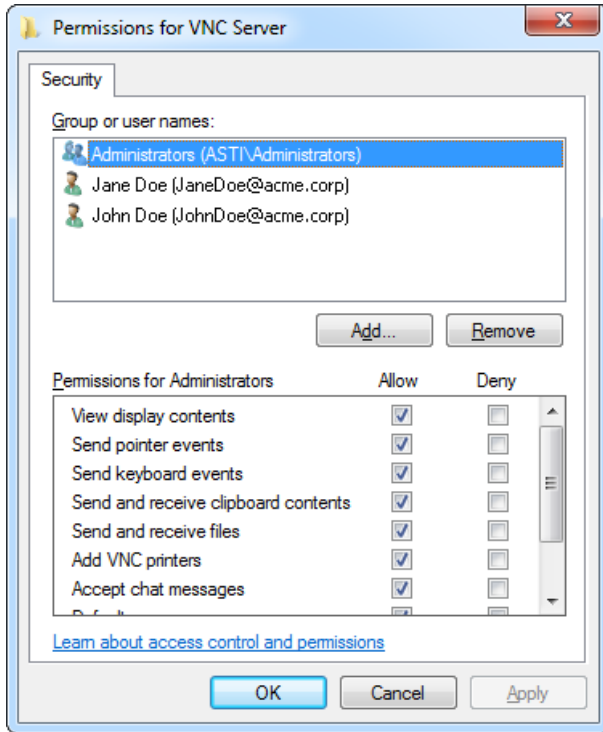

Permission name	When granted, a connected user can...	Full	Default	View Only
View display contents	See the host computer's desktop.	YES	YES	YES
Send pointer events	Control the host computer using the client computer's mouse.	YES	YES	
Send keyboard events	Control the host computer using the client computer's keyboard.	YES	YES	
Send and receive clipboard contents	Copy and paste text between applications running on the client and host computers.	YES	YES	
Send and receive files	Exchange files with the host computer.	YES	YES	
Add VNC printers	Print host computer files to a local printer.	YES	YES	
Accept chat messages	Chat with other <i>VNC Viewer</i> users, or with a host computer user.	YES	YES	
Connect without accept/reject prompt	Bypass connection prompts. For more information about this feature, see <i>Preventing particular users connecting</i> on page 113.	YES		

Customizing VNC permissions

You can customize VNC permissions for particular users, perhaps in order to revoke permissions for certain RealVNC remote control features while just those users are connected.

Note: You can restrict access to RealVNC remote control features for *all* connected users by configuring options on the **Inputs** tab of the **VNC Server - Options** dialog. For more information, see *Restricting functionality for connected users* on page 93.

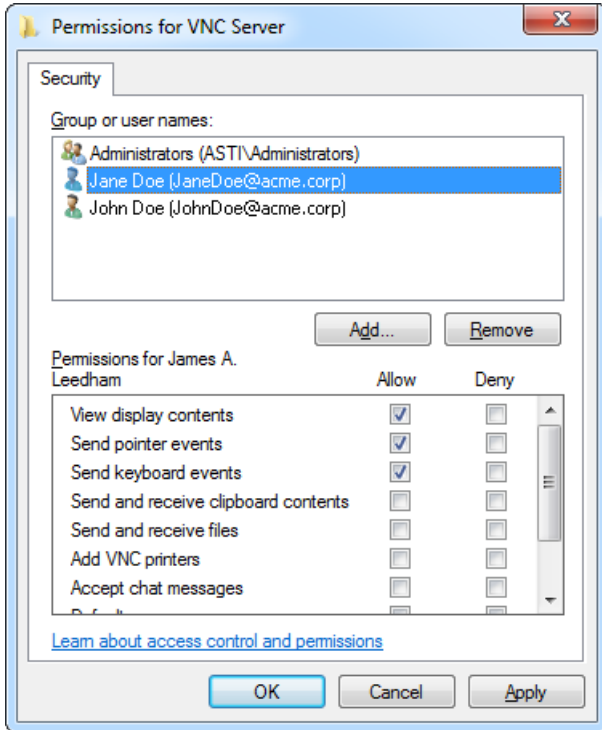

To customize VNC permissions, open the **VNC Server - Options** dialog. *More on this dialog.* Make sure either `Windows password` (or platform-specific equivalent) or `Single sign-on` is selected in the **Authentication** dropdown on the **Connections** tab, and click the **Configure** button:

Note: A user can supply the credentials of any of the host computer users listed in **Group or user names** in order to connect to VNC Server (including any member of a group). To see how to configure host computer users or groups, see *Managing users and groups in the authentication list* on page 102.

You can change the VNC permissions allocated to a particular host computer user. To do this, select the appropriate entry in the **Group or user names** list, and turn individual permissions on or off. For example, in

the following dialog, just the View display contents, Send pointer events, and Send keyboard events permissions are turned on for the host computer user Jane Doe:

This means that any user supplying Jane Doe's credentials in order to connect to *VNC Server* is able to see the host computer's desktop, and control it using their keyboard and mouse. All other RealVNC remote control features, however, are disabled. A user will not be able to copy and paste text, print, chat, transfer files, or bypass connection prompts.

Uniquely identifying VNC Server

VNC Server (Enterprise) and *VNC Server (Personal)* have a uniquely identifying signature:

- Under Windows and Mac OS X, this signature uniquely identifies *VNC Server* among all instances running on the same host computer.
- Under UNIX/Linux, this signature is shared by instances of *VNC Server* started by the same host computer user.

Note: *VNC Server (Free)* does not have a unique signature. Upgrade the host computer to *VNC Server (Enterprise)* or *VNC Server (Personal)* if security is important to you.

The *VNC Server* signature is displayed in the **Get Started** area of the **VNC Server** dialog. *More on this dialog.*

When a user connects from a particular client computer for the first time, this signature is published. The user is asked to verify that the signature they see matches that of *VNC Server*. See *Checking the signature* on page 24 for more information.

A *VNC Server* signature should not change. The next (and all subsequent) times a user connects from the same client computer, the signature is *not* published. If the signature changes, it may be because a third party is interrupting the connection between client and host computers and eavesdropping on communications – a so-called ‘man-in-the-middle’ attack. If a user sees a message similar to the following:

```
WARNING: VNC Server's signature has changed since you last connected to it.
```

```
Unless there is a good reason for the signature to have changed, you should not continue connecting.
```

```
The new VNC Server signature is fa-a5-76-c9-3d-df-ca-1d.
```

```
Do you wish to accept the new signature and continue connecting?
```

then it is recommended that they *do not* connect.

Note: The signature *does* change if *VNC Server* is re-installed on the host computer.

Protecting privacy

Note: The information in this section applies to *VNC Server* for Windows only.

By default, *VNC Server* promotes shared connections. That is to say, if more than one user is connected, all users can observe each other's operations, and if a host computer user is present, then that user can observe the operations of connected users.

Under Windows, you can configure *VNC Server* to uphold the privacy of connected users by editing various options in the **VNC Server - Options** dialog. *More on this dialog.*

Blanking the host computer's monitor

You can blank the host computer's monitor in order to prevent a host computer user observing the operations of connected users. To do this, turn on **Blank the screen while VNC Viewers are connected**. This option is on the **Desktop** tab.

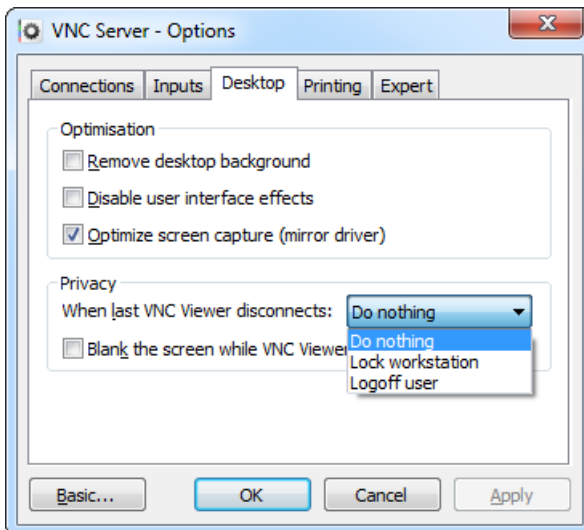

Preventing input from the host computer

You can disable the keyboard and mouse of the host computer in order to prevent a host computer user interrupting the operations of connected users. To do this, turn on **Disable the keyboard and mouse while VNC Viewers are connected**. This option is on the **Inputs** tab.

Protecting the host computer

Note: The information in this section applies to *VNC Server* in Service Mode only.

You can protect the host computer when no connections are in progress by locking it or logging off when the last user disconnects. To do this, select an alternative to the default *Do nothing* option from the **When last VNC Viewer disconnects** dropdown on the **Desktop** tab:

To protect the host computer by:

- Locking the workstation, select *Lock workstation*. Users can immediately reconnect, but must know how to unlock the host computer in order to continue. Note that if you apply this setting to *VNC Server* in User Mode, users can reconnect but see only a non-operational black screen, and cannot continue.
- Logging off, select *Logoff user*. Users can immediately reconnect, but must know how to log on to the host computer in order to continue.

Saving Connections

This appendix explains how to use *VNC Viewer* to save connections so you can quickly connect to favorite host computers again with just a few mouse clicks.

Note: You can save connections to desktop icons, and to *VNC Address Book* if you installed *VNC* on the client computer. See *Setting up the client computer on page 12* for more information.

A saved connection remembers the network address of the host computer and the authentication credentials required to connect to *VNC Server*, so you do not have to, and automatically recreates your preferred working environment each time.

Contents

Saving connections to VNC Address Book	122
Using VNC Address Book to connect	127
Managing connections using VNC Address Book	128
Saving connections to desktop icons	131

Saving connections to VNC Address Book

You can save connections to *VNC Address Book* if you installed *VNC* on the client computer. For more information, see *Setting up the client computer* on page 12.

Note: If *VNC Address Book* is not available, you can save connections to desktop icons. This is equally convenient but may be less secure. See *Saving connections to desktop icons* on page 131.

When you save a connection, you can subsequently use *VNC Address Book* to connect to that host computer instead of *VNC Viewer*. This means you do not have to remember the network address of the host computer or the port number for *VNC Server*, nor a user name and password. In addition, *VNC Address Book* automatically recreates the *VNC Viewer* environment you chose for controlling that host computer last time, for example the scaling applied to the desktop, the encryption level, and the color quality.

Note: Because *VNC Address Book* stores *VNC Server* authentication credentials, access to it is controlled by a *master password*. For more information, see *Working with the master password* on page 130.

You can additionally use *VNC Address Book* to organize connections, configure the appearance and behavior of *VNC Viewer* for particular connections, and share connections with other *VNC Viewer* users.

Saving the current connection

If you are connected to a host computer, you can save the current connection to *VNC Address Book* at any time. To do this:

1. Click the **Save Connection**  *VNC Viewer* toolbar button. *VNC Address Book* opens. If you entered a password in order to connect to *VNC Server*, you are prompted to save it:

Choose:

- **Don't save VNC Server password** in order to forget the password. You will need to enter it each time you use *VNC Address Book* to connect.
- **Save VNC Server password** to save the password in obfuscated, though not encrypted, form. You will no longer need to remember the password. However, since the connection will not be protected by the *VNC Address Book* master password, any other user of your client computer will also be able to connect.
- **Encrypt VNC Server password** to create a *protected connection* in which the password is both saved and encrypted. You will no longer need to remember it. You will, however, have to enter the

VNC Address Book master password in order to connect (and also to edit the connection). Note that a protected connection is identified by a padlock symbol  throughout VNC Address Book.

- Click the **OK** button. If you chose to create a protected connection, and this is the first time you have used VNC Address Book, you are prompted to specify a master password:

- Click the **OK** button. The connection is saved to VNC Address Book:

To see how to use VNC Address Book to connect to this host computer again, read *Using VNC Address Book to connect* on page 127.

For more information on editing and organizing connections, start with *Organizing connections* on page 129.

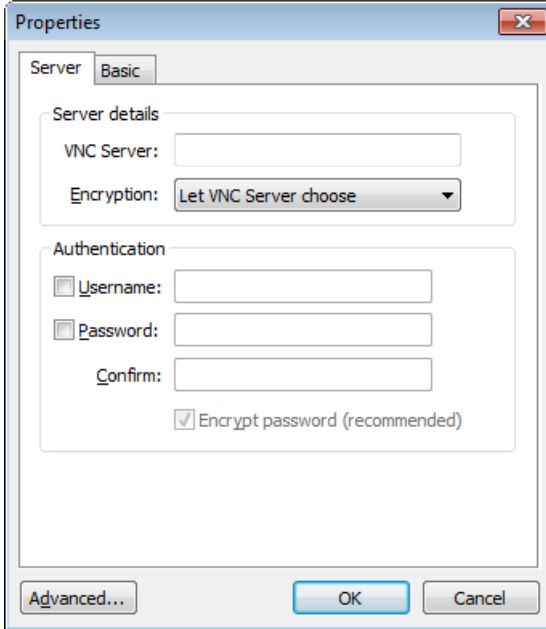

Creating a new connection

You can create a connection in *VNC Address Book* directly. To do this:

1. Start *VNC Address Book* on the client computer. See *how to do this*. The **VNC Address Book** dialog opens:

2. Click the **New Entry**  toolbar button. The **Properties** dialog opens:

3. Enter a network address for the host computer in the **VNC Server** field (including a port number if necessary), choose an **Encryption** option (or retain the default) and, optionally, specify your VNC Server user name and password in the **Authentication** area. To see how to find out this information, start with *Step 3: Identify VNC Server running on the host computer on page 21*.

By default, VNC Address Book creates a *protected connection*. This means you must enter the VNC Address Book master password in order to connect to the host computer, and also to edit the connection. A protected connection is identified by a padlock symbol  throughout VNC Address Book.

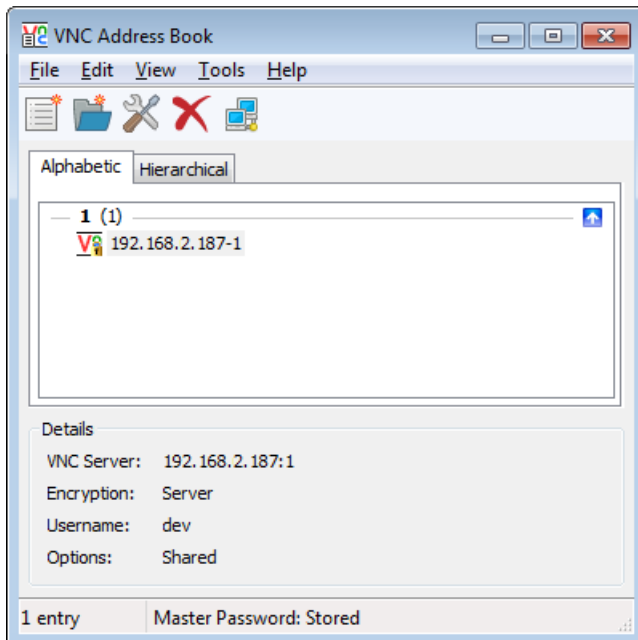

Note: Turn off **Encrypt password (recommended)** if you do not want to enter the VNC Address Book master password in order to connect. Note this may constitute a security risk if others use your client computer.

You can optionally edit VNC Viewer options in order to set up your preferred environment for controlling this host computer. To do this, use the **Basic** tab to configure common options, or click the **Advanced** button to see all the tabs. For more information, start with *Configuring VNC Viewer before you connect on page 35*.

- Click the **OK** button. If you chose to create a protected connection, and this is the first time you have used *VNC Address Book*, you are prompted to specify a master password:

- Click the **OK** button. The connection is saved to *VNC Address Book*:

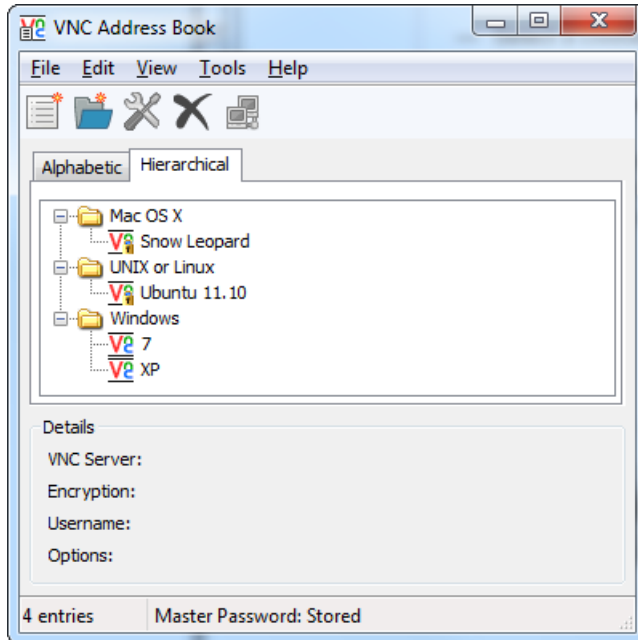

To see how to use *VNC Address Book* to connect to this host computer, read *Using VNC Address Book to connect* on page 127.

For more information on editing and organizing connections, start with *Organizing connections* on page 129.

Using VNC Address Book to connect

You can use *VNC Address Book* to quickly connect to a host computer. To do this:

1. Start *VNC Address Book* on the client computer. See *how to do this*. The **VNC Address Book** dialog opens:

2. Either:

- Double-click a connection in the **Alphabetic** or **Hierarchical** list.
- Select a connection in a list and click the **Connect**  toolbar button.

You may be required to enter the *VNC Address Book* master password in order to connect. For more information, see *Working with the master password* on page 130.

Under Windows, when *VNC Address Book* starts, a *VNC Address Book* icon  is displayed in the Notification area. This icon provides further options for quickly and conveniently connecting to host computers. For more information, see *Working with VNC Address Book* on page 128.

Managing connections using VNC Address Book

This section explains *VNC Address Book* features and operations.

Starting VNC Address Book

To start *VNC Address Book*:

- Under Windows, select **RealVNC > VNC Address Book** from the **Start** menu.
Note: Under Windows, you can start *VNC Address Book* automatically when the computer is powered on. To do this, select **Tools > Options** and, in the **UI behavior** area, turn on **Start with Windows**.
- Under UNIX/Linux, select **Applications > Internet > VNC Address Book** from the menu system, or search for this application using the standard operating system facility.
Note: If no menu system or search facility is available, open a Terminal window, run the command `vncaddrbook`, and press the ENTER key. Note you should *not* do this as a user with administrative privileges.
- Under Mac OS X, navigate to the **Applications > RealVNC** folder, and double-click the **VNC Address Book** program.

Working with VNC Address Book

Under Windows, while *VNC Address Book* is running, a *VNC Address Book* icon  is displayed in the Notification area. Under Windows 7, note this is hidden by default and accessible from  to the right of the Taskbar:

Under Windows XP, the icon may be hidden by other icons.

Note: Under UNIX/Linux and Mac OS X, no *VNC Address Book* icon is available. However, most operations explained below can be performed from the **VNC Address Book** dialog.

The *VNC Address Book* icon:

- Provides visual confirmation that *VNC Address Book* is running on the client computer. If the icon is not available, then *VNC Address Book* is not running.

- Has a shortcut menu that performs useful operations:

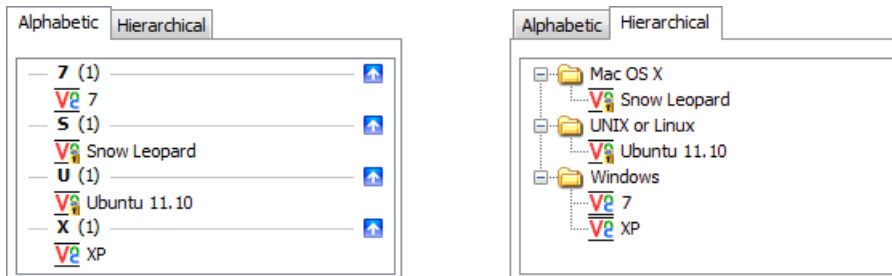

The following table explains the effect of selecting each *VNC Address Book* shortcut menu option.

Option	Purpose
Connect to	Choose a host computer to connect to.
Launch VNC Viewer	Start <i>VNC Viewer</i> , enabling you to connect to a new host computer in the standard way. For more information, see <i>Connecting to a host computer</i> on page 37.
Open Address Book	Create new connections or edit and organize existing ones. (Alternatively, double-click the <i>VNC Address Book</i> icon to open the VNC Address Book dialog.)
Exit	Close <i>VNC Address Book</i> .

Organizing connections

VNC Address Book organizes connections both alphabetically and hierarchically:

You can reorganize connections in the **Hierarchical** list. (The **Alphabetic** list is automatically organized.)

Click the **New Folder**  toolbar button to create folders in the **Hierarchical** list. You can drag-and-drop connections to, from, and between folders. Note that if you delete a folder, all connections in that folder are deleted too.

Editing connections

You can edit an existing connection. Note you may be required to enter the *VNC Address Book* master password first.

To do this, select a connection in the **Alphabetic** or **Hierarchical** list, and either:

- Click the **Properties**  toolbar button.
- Select **Edit > Properties**.

For more information on editing *VNC Viewer* options, start with *Configuring VNC Viewer before you connect* on page 35.

To rename a connection in *VNC Address Book*, select it in the **Alphabetic** or **Hierarchical** list and select **Edit > Rename**, or right-click and select **Rename** from the shortcut menu.

Sharing connections

You can share one or more connections with other fully-featured *VNC Viewer* users. Note that *VNC Server* passwords are also shared, albeit in obfuscated or encrypted form.

To share:

- All *VNC Address Book* connections, select **Tools > Export Address Book**.
- A single connection, right-click it in the **Alphabetic** or **Hierarchical** list and, from the shortcut menu, select **Export**.

Choose a location for the exported file. If the file contains a protected connection (one in which the *VNC Server* password was saved and encrypted), the recipient will need your *VNC Address Book* master password in order to import it.

You can import one or more connections shared by other fully-featured *VNC Viewer* users. To do this, select **Tools > Import Address Book**, and select the file to import. If the file contains a protected connection, you will need the *VNC Address Book* master password of the user who created the file in order to import it.

Removing connections

To remove a connection, select it in the **Alphabetic** or **Hierarchical** list, and either:

- Click the **Delete**  toolbar button.
- Select **Edit > Delete**.

Working with the master password

If you chose to encrypt a *VNC Server* password when you saved a connection to a host computer, you created a *protected connection*.

VNC Address Book secures protected connections using the *master password*. You must enter the master password in order to perform an operation on a protected connection, for example connecting to the host computer, or editing the connection.

Note: You do not have to enter the master password in order to perform operations on connections for which the *VNC Server* password was not saved, or was saved in obfuscated, though not encrypted, form. For more information on saving *VNC Server* passwords, start with *Saving the current connection* on page 122.

By default, *VNC Address Book* remembers the master password for one hour. This means you have sixty minutes after you first enter it in order to perform an operation on a protected connection. To change this, and *require* the entry of the master password, select:

- **Tools > Forget Master Password** to require the entry of the master password for the next operation on a protected connection.

- **Tools > Options** and, in the **Master password** area, turn off **Remember for** to require the entry of the master password for all future operations on protected connections. (Alternatively, you can decrease the length of time the master password is remembered.)

Note: The Status Bar reports `Master Password: Stored` if you do not currently need to enter the master password, and `Master Password: Required` if you do.

To change the master password, select **Tools > Options** and, in the **Master password** area, click the **Change** button.

Saving connections to desktop icons

You can save the current connection to a desktop icon on the client computer:

A desktop icon provides an extremely quick and convenient way of connecting to a host computer. Simply double-click the icon to connect. Your preferred *VNC Viewer* environment for controlling the host computer is automatically recreated.

Note: You may need to associate the desktop icon with the *VNC Viewer* executable file the first time you double-click an icon connect.

To save the current connection as a desktop icon:

1. Click the **Save Connection**  *VNC Viewer* toolbar button.

Note: If *VNC Address Book* is installed on the client computer, you must first disable it. To do this, click the **Options**  *VNC Viewer* toolbar button to open the **Options** dialog and, on the **Expert** tab, set the `UseAddrBook` parameter to `False`.

2. If you entered a password in order to connect to *VNC Server*, you are prompted to save the password. Note that doing so may constitute a security risk, since the password is saved in obfuscated, though not encrypted, form. If you do not save the password, you must enter it each time you connect.
3. Choose a location to save the icon file to (for example, the desktop), and an intuitive name.
